1.0 INTRODUCTION

This study provides hydraulic models and as-built plans in support of the Letter of Map Revision for the Flamingo Wash improvements from Mojave Road to Boulder Highway in Clark County, Nevada. The flood control improvements were constructed in two phases. The first phase involved reconstruction of the Boulder Highway Bridge at Flamingo Wash and included concrete transition structures upstream and downstream of the bridge (see Photo 2 Appendix B). The second phase consisted of concrete lining the wash between Boulder Highway and Mojave Road (see Photo 1 Appendix B).

2.0 PRE-PROJECT CONDITIONS

Previous to construction of the Flamingo Wash Phase I and II improvements, the reinforced box culverts at Boulder Highway did not have the capacity to convey the 100-year flood. The wash between Mojave Road and Boulder Highway was earthen without erosion protection. In July 1999, floodwater caused severe erosion of the banks in the project reach and overtopped the Boulder Highway Bridge.

Figure 1 of Appendix B shows the limits of the pre-project (effective) 100-year special flood hazard area, Zone A, reflecting the backwater at the Boulder Highway bridge. The effective 100-year flow in the project reach is 5,800 cfs between Mojave Road and Boulder Highway, and 6,300 cfs downstream of Boulder Highway. The effective special flood hazard area was modeled and delineated in the 1997 Flood Insurance Study (FIS) Restudy for the Flamingo Wash in Clark County, Nevada prepared by G.C. Wallace Inc. for the Clark County Regional Flood Control District.

3.0 POST-PROJECT CONDITIONS

Phase I of the Flamingo Wash improvements included the construction of the Boulder Highway Bridge. As part of the Phase I improvements, the three 7 ft x 11 ft box culverts under Boulder Highway were replaced with a double span bridge. The new bridge has an opening height of 7.7 ft, a span of 75 ft, and a 3 ft wide pier in the center. The total open area is 575 square feet.

Phase II was a channel lining project from Mojave Road to Boulder Highway. The concrete channel lining included both rectangular and trapezoidal sections. The rectangular section begins at Boulder Highway and consists of a 60 ft wide concrete rectangular channel that varies in height from 7.6 ft to 8.7 ft. The

rectangular channel then transitions into a 7 ft deep concrete trapezoidal channel with a 60' wide bottom and 2:1 side slopes.

As-built plans of the Phase I and II improvements are included in Appendix D. It should be noted that the HGL shown on the as-built plans is based on the channel 100-year design flow of 6,600 cfs. The 6,600 cfs is based on a future development in the upstream watershed.

With construction of the Flamingo Wash Phase I and II improvements, the 100-year flood is now contained within the channel as shown on the annotated FIRM, Figure 2 of Appendix B.

4.0 HYDRAULIC MODELS

4.2 Effective and Corrective Effective HEC-2 Models

Two hydraulic models, subcritical and supercritical, were prepared in the FIS for the reach of Flamingo Wash between Eastern Avenue and US 95 (aka I-515). Models were prepared using the US Army Corps of Engineers HEC-2 Water Surface Profile computer program.

Since the existing wash in the project reach was previously unlined, the subcritical model established the effective base flood elevations (BFEs). However, upstream of Mojave Road, the wash is concrete lined and the supercritical model established the effective BFEs.

For this study, the basic input for the effective FIS models was used with two modifications. First, the effective subcritical model was truncated to eliminate irrelevant sections, maintaining only the sections in the vicinity of the project improvements. All five sections of the effective FIS supercritical model were used in this study. Second, the elevations were raised by a factor of 2.26 ft to adjust them from the National Geodetic Vertical Datum of 1929 (NGVD29) to the North America Vertical Datum of 1988 (NAVD88). Datum conversion calculations are provided in Appendix C.

The modified FIS models are referred to herein as the "corrected" effective models. Both the effective and corrected effective HEC-2 models are provided in Appendix C.

4.2 Post-Project HEC-RAS Model

For post-project conditions, the study reach was modeled with HEC-RAS using the supercritical flow option. The results show that supercritical flow is maintained throughout the project length and that the flow is contained within the concrete channel walls and under the Boulder Highway Bridge.

Figures 3a and 3b in Appendix B are work maps showing the locations of the model cross-sections, the effective and revised Zone A boundaries, and the upstream and downstream limits of this study. On Figures 3a and 3b, circled station numbers were taken directly from the corrected effective FIS model, and those enclosed by a square were created for the purposes of this study.

The limits of the post-project models were extended upstream and downstream of the project improvements a sufficient distance to "tie" into the effective corrected FIS models. At the upstream end, the post-project model ties into the supercritical corrective effective FIS model at Station 640, BFE equal to 1862.90 ft (critical depth). The post-project model ties into the subcritical corrected effective FIS model at Station 390, BFE equal to 1797.18 ft (critical depth).

5.0 CONCLUSION

Project improvements, including the Boulder Highway Bridge and concrete channel lining, were incorporated into the corrected effective FIS HEC-1 model. The results of the hydraulic analysis indicate that the 100-year flood will be contained within the channel for the entire length of the project.

3. Pre-Submittal Review of Hydraulic Models

FEMA has developed two review programs, CHECK-2 and CHECK-RAS, to aid in the review of HEC-2 and HEC-RAS hydraulic models, respectively. These review programs verify that the hydraulic estimates and assumptions in the model data are in accordance with NFIP requirements, and that the data are comparable with the assumptions and limitations of HEC-2/HEC-RAS. CHECK-2 and CHECK-RAS identify areas of potential error or concern. These tools do not replace engineering judgment. CHECK-2 and CHECK-RAS can be downloaded from http://www.fema.gov/fhm/frm_soft.shtm. We recommend that you review your HEC-2 and HEC-RAS models with CHECK-2 and CHECK-RAS. If you disagree with a message, please attach an explanation of why the message is not valid in this case. Review of your submittal and resolution of valid modeling discrepancies will result in reduced review time.

F. SEDIMENT TRANSPORT

Flooding Source:

Name of Structure:

If there is any indication from historical records that sediment transport (including scour and deposition) can affect the Base Flood Elevation (BFE); and/or based on the stream morphology, vegetative cover, development of the watershed and bank conditions, there is a potential for debris and sediment transport (including scour and deposition) to affect the BFEs, then provide the following information along with the supporting documentation:

Sediment load associated with the base flood discharge: Volume acre-feet

Debris load associated with the base flood discharge: Volume acre-feet

Sediment transport rate (percent concentration by volume)

Method used to estimate sediment transport:

Most sediment transport formulas are intended for a range of hydraulic conditions and sediment sizes; attach a detailed explanation for using the selected method.

Method used to estimate scour and/or deposition:

Method used to revise hydraulic or hydrologic analysis (model) to account for sediment transport:
Please note that bulked flows are used to evaluate the performance of a structure during the base flood; however, FEMA does not map BFEs based on bulked flows.

If a sediment analysis has not been performed, an explanation as to why sediment transport (including scour and deposition) will not affect the BFEs or structures must be provided.

Warning: The velocity head has changed by more than 0.5 ft (0.15 m). This may indicate the need for additional cross sections.
Warning: The conveyance ratio (upstream conveyance divided by downstream conveyance) is less than 0.7 or greater than 1.4. This may indicate the need for additional cross sections.
Warning: The energy loss was greater than 1.0 ft (0.3 m). between the current and previous cross section. This may indicate the need for additional cross sections.
