FEDERAL EMERGENCY MANAGEMENT AGENCY **REVISION REQUESTOR AND COMMUNITY OFFICIAL FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 2.13 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

1. OVERVIEW

1. The basis for this revision request is (are): *(check all that apply)*
   - ☒ Physical change
     - ☒ Existing
     - ☒ Proposed
   - ☐ Improved methodology
   - ☐ Improved data
   - ☐ Floodway revision
   - ☐ Other

   Explain
2. Flooding Source: **Range Wash**
3. Project Name/Identifier: **West Range Wash Dike, Range Wash/Sloan Channel Confluence Detention Basin**
4. FEMA zone designations affected: **ZONE A**
   (example: A, AH, AO. A1-30, A99, AE, V, V1-30, VE, B, C, D, X)
5. The NFIP map panel(s) affected for all impacted communities is (are):

Community No.	Community Name	County	State	Map No.	Panel No.	Effective Date
EX: 480301	Katy, City	Harris, Fort Bend	TX	480301	0005D	02/08/83
320007	**North Las Vegas, City**	**Clark**	**NV**	**32003C**	**1790 D**	**8/16/95**
320007	**North Las Vegas, City**	**Clark**	**NV**	**32003C**	**2176 D**	**8/16/95**
320003	**Clark County**	**Clark**	**NV**	**32003C**	**2180 D**	**8/16/95**
320007	**North Las Vegas, City**	**Clark**	**NV**	**32003C**	**2180 D**	**8/16/95**
320003	**Clark County**	**Clark**	**NV**	**32003C**	**2200 D**	**8/16/95**

6. The area of revision encompasses the following types of flooding, structures, and associated disciplines: *(check all that apply)*

Types of Flooding

- ☒ Riverine
- ☐ Coastal
- ☐ Alluvial Fan
- ☐ Shallow Flooding *(e.g. Zones AO and AH)*
- ☐ Lakes

Affected by wind/wave action
- ☐ Yes
- ☐ No

Structures

- ☒ Channelization
- ☒ Levee/Floodwall
- ☐ Bridge/Culvert
- ☒ Dam
- ☐ Coastal
- ☒ Fill
- ☐ Pump Station
- ☐ None
- ☐ Channel Relocation
- ☐ Excavation
- ☐ Other *(describe)*

Disciplines*

- ☒ Water Resources
  - ☒ Hydrology
  - ☒ Hydraulics
  - ☒ Sediment Transport
  - ☐ Interior Drainage
- ☐ Structural
- ☐ Geotechnical
- ☐ Land Surveying
- ☐ Other *(describe)*

☐ Other (describe) _____ _____ **CIVIL ENGINEER**

*** Attach completed "Certification by Registered Professional Engineer and/or Land Surveyor" Form for each discipline checked. (Form 2)**

2. FLOODWAY INFORMATION

7. Does the affected flooding source have a floodway designated on the effective FIRM or FBFM? ☐ Yes ☒ No
8. Does the revised floodway delineation differ from that shown on the effective FIRM or FBFM ☐ Yes ☒ No
   If yes, give reason:

Attach copy of either a public notice distributed by the community stating the community's intent to revise the floodway or a statement by the community that it has notified all affected property owners and affected adjacent jurisdictions

9. Does the state have jurisdiction over the floodway or its adoption by communities participating in the NFIP?
☐ Yes ☒ No

If yes, attach a copy of a letter notifying the appropriate State agency of the floodway revision and documentation of the approval of the revised floodway by the appropriate State agency.

3. PROPOSED ENCROACHMENTS

10. With floodways:

1A. Does the revision request involve fill, new construction, substantial improvements, or other development in the floodway? ☐ Yes ☐ No

1B If yes, does the development cause the 100-year water surface elevation to increase at any location by more that 0.000 feet? ☐ Yes ☐ No

11. Without floodways:

2A. Does the revision request involve fill, new construction, substantial improvements, or other development in the 100-year floodplain? ☒ Yes ☐ No

2B If yes, does the cumulative effect of all development that has occurred since the effective SFHA was originally identified cause the 100-year water surface elevation to increase at any location by more than one foot *(or other surcharge limit if community or state has adopted more stringent criteria)?* ☐ Yes ☒ No

If the answer to either Items 1B or 2B is yes, please provide documentation that all requirements of Section 65.12 of the NFIP regulations have been met, regarding evaluation of alternatives, notice to individual legal property owners, concurrence of CEO, and certification that no insurable structures are impacted.

4. REVISION REQUESTOR ACKNOWLEDGMENT

12. Having read NFIP Regulations, 44 CFR Ch.1, parts 59, 60, 61, and 72, I believe that the proposed revision ☒ is ☐ is not in compliance with the requirements of the aforementioned NFIP Regulations.

5. COMMUNITY OFFICIAL ACKNOWLEDGMENT

13. Was this revision request reviewed by the community for compliance with the community's adopted floodplain management ordinances? ☒ Yes ☐ No

14. Does this revision request have the endorsement of the community? ☒ Yes ☐ No

If no to either of the above questions, please explain: _____

Please note that community acknowledgment and/or notification is required for all requests as outlined in Section 65.4 (b) of the NFIP Regulations.

6. OPERATION AND MAINTENANCE

15. Does the physical change involve a flood control structure (e.g., levees, floodwalls, channelization, basins, dams)?
☒ Yes ☐ No

If yes, please provide the following information for each of the new flood control structures:

A. Inspection of the flood control project will be conducted periodically by **Clark County Regional Flood Control District** (entity) with a maximum interval of **12** months between inspections.

B. Based on the results of scheduled periodic inspections, appropriate maintenance of the flood control facilities will be conducted by **City of North Las Vegas and Clark County Department of Public Works** (entity) to ensure the integrity and degree of flood protection of the structure

C. A formal plan of operation, including documentation of the flood warning system, specifications and assignments of responsibility by individual name or title, and provisions for testing the plan at intervals not less than one year, ☒ has ☐ has not been prepared for the flood control structure.

D. The community is willing to assume responsibility for ☒ performing ☒ overseeing compliance with the maintenance and operation plan of the **West Range Wash Dike, Range/Sloan Confluence Detention Basin**
(Name)
flood control structure. If not performed promptly by an owner other than the community, the community will provide the necessary services without cost to the Federal government.

Attach operation and maintenance plans

7. REQUESTED RESPONSE FROM FEMA

16. After examining the pertinent NFIP regulations and reviewing the document entitled " Appeals, Revisions, and Amendments to Flood Insurance Maps: A guide for Community Officials," dated January 1990, this request is for a:

X	a.	CLOMR	A letter from FEMA commenting on whether a proposed project, if built as proposed, would justify a map revision *(LOMR or PMR)*, or proposed hydrology changes *(see 44 CFR Ch.I, Parts 60, 65, and 72).*
X	b.	LOMR	A letter from FEMA officially revising the current NFIP map to show changes in floodplain, floodways, or flood elevations. LOMRs typically depict decreased flood hazards. *(see 44 CFR Ch.I Parts 60 and 65.)*
	c.	PMR	A reprinted NFIP map incorporating changes to flood plains, floodways, or flood elevations Because of the time and cost involved to change, reprint, and redistribute an NFIP map, a PMR is usually processed when a revision reflects increased flood hazards or large-scope changes. *(See 44 CFR Ch.I, Parts 60 and 65.)*
	d.	Other	Describe _____

8. FORMS INCLUDED

17. Form 2 entitled, "Certification By Registered Professional Engineer and/or Land Surveyor" must be submitted.

The following forms should be included with this request if (check the included forms):

• Hydrologic analysis for flooding source differs from that used to develop FIRM	☒ Hydrologic Analysis Form (Form 3)
• Hydraulic analysis for riverine flooding differs from that used to develop FIRM	☒ Riverine Hydraulic Analysis Form (Form 4)
• The request is based on updated topographic information or a revised floodplain or floodway delineation is requested	☒ Riverine/Coastal Mapping Form (Form 5)
• The request involves any type of channel modification	☒ Channelization Form (Form 6)
• The request involves new bridge or culvert or revised analysis of an existing bridge or culvert	☐ Bridge/Culvert Form (Form 7)
• The request involves a new levee/floodwall system	☒ Levee/Floodwall System Analysis Form (Form 8)
• The request involves analysis of coastal flooding	☐ Coastal Analysis Form (Form 9)
• The request involves coastal structures credited as providing protection from the 100-year flood	☐ Coastal Structures (Form 10)
• The request involves an existing, proposed, or modified dam	☒ Dam Form (Form 11)
• The request involves structures credited as providing protection from the 100-year flood on an alluvial fan	☐ Alluvial Fan Flooding Form (Form 12)

9. INITIAL REVIEW FEE

18. The Minimum initial review fee for the appropriate request category has been included. ☐ Yes ☒ No
Initial fee amount: $ _____

Check or money order only. Make check or money order payable to: National Flood Insurance Program. If paying by Visa or Mastercard please refer to the credit card information form which follows this form.

or

19. This request is for a project that is for public benefit and is primarily intended for flood loss reduction to insurable structures in identified flood hazard areas which were in existence prior to the commencement of construction of the flood control project. ☒ Yes ☐ No

or

20. This request is to correct map errors, to include the effects of natural changes within the areas of special flood hazard, or solely to provide more detailed data. ☐ Yes ☒ No

Note: I understand that my signature indicates that all information submitted in support of this request is correct.

Donald W. Davis
Signature of Revision Requester

Donald W. Davis, P.E., Project Manager

Does this request impact any other communities? ☒ Yes ☐ No

If yes, attach letters from all affected jurisdictions acknowledging revision request and approving changes to floodway, if applicable.

Note: Although a photograph of physical changes is not required, it may be helpful for FEMA's review.

FEDERAL EMERGENCY MANAGEMENT AGENCY **CERTIFICATION BY REGISTERED PROFESSIONAL ENGINEER AND/OR LAND SURVEYOR FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average .23 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

1. This certification is in accordance with 44 CFR Ch. I, Section 65.2

2. I am licensed with an expertise in **water resources (hydrology, hydraulics)**
   [example: water resources *(hydrology, hydraulics, sediment transport, interior drainage)** structural, *geotechnical, land surveying.*]

3. I have **13** years experience in the expertise listed above.

4. I have ☐ prepared ☒ reviewed the attached supporting data and analyses related to my expertise.

5. I ☒ have ☐ have not visited and physically viewed the project.

6. In my opinion, the following analyses and/or designs, is/are being certified:
   West Range Wash Dike, Confluence Detention Basin, Sloan Channel Owens to Stewart, Channel Lamb to Alexander

7. Based upon the following review, the modifications in place have been constructed in general concordance with plans and specifications.

   Basis for above statement: (check all that apply)
   - a. ☐ Viewed all phases of actual construction.
   - b. ☒ Compared plans and specifications with as-built survey information.
   - c. ☒ Examined plans and specifications and compared with competed projects.
   - d. ☐ Other _____

8. All information submitted in support of this request is correct to the best of my knowledge. I understand that any false statement may be punishable by fine or imprisonment under title 18 of the United States Code, Section 1001.

Note: Insert not applicable (N/A) when statement does not apply.

FEDERAL EMERGENCY MANAGEMENT AGENCY **HYDROLOGIC ANALYSIS FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 3.67 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

Community Name: **Clark County Nevada and Incorporated Areas, City of North Las Vegas**

Flooding Source: **Range Wash**

(One form for each flooding source)

Project Name / Identifier: **Range Wash FIS Restudy**

1. HYDROLOGIC ANALYSIS IN FIS

- ☒ Approximate study stream (Zone A)
- ☐ Detailed study stream (briefly explain methodology) _____

2. REASON FOR NEW HYDROLOGIC ANALYSIS

- ☐ No existing analysis
- ☒ Improved Data *(see data revision on page 3)*
- ☒ Changed physical conditions of watershed *(explain)* **Major flood control facilities have been constructed or are under construction, including a diversion dike to the North Las Vegas Detention Basin and the Range Wash/Sloan Channel Confluence Detention Basin**
- ☐ Alternative methodology *(justify why the revised model is better than model used in the effective **FIS**)*
- ☒ Evaluation of proposed conditions (CLOMRs only) (explain) **The Confluence Detention Basin is presently under construction**
- ☐ Other _____

If a computer program/model was used in revising the hydrologic analysis, please provide a diskette with the input files for the 10-, 50-, 100- and 500-year recurrence intervals.

Only the 100-year recurrence interval need be included for SFHA designated as Zone A.

3. APPROVAL OF ANALYSIS

- ☒ Approval of hydrologic analysis, including the resulting peak discharge value (s) has been provided by the appropriate local, state, or Federal Agency. (i.e., **Clark County Regional Flood Control District**)

  Attach evidence of approval.
- ☐ Approval of the hydrologic analysis is not required by any local, state, or Federal Agency.

4. REVIEW OF RESULTS

Stream: **Range Wash**

Comparison of 100-year Discharges

Location:	Drainage area (Sq. mi.) w/o dike - w/ dike - w/ DB	FIS (cfs): w/o dike - w/ dike	Revised (cfs): w/ dike - w/ DB
West Tributary at Las Vegas Blvd	49 - 11, 8_R - N/A	6,300 - 2,900	1,550
Sloan Channel at Owens	138 - 89 - 85_R	8,000 - 5,200	1,940
Sloan Channel at Las Vegas Wash	151 - 102 - 16	8,300 - 6,000	4,000
$_R$: *Revised areas of Restudy*			

Note: When revised discharges are not significantly different than FIS discharges, FEMA may require a confidence limits analysis on attachment D at a later date to complete the review

As is often the case with revision requests, only a portion of a stream may actually be revised or be affected by a revision. Therefore, transition to the unrevised portion is important to maintain the continuity of the study. NFIP regulations stipulate that such a transition must be assured. What is the transition from the proposed discharges to the effective discharges? Please explain how the transition was made *(attach separate sheet if necessary)*

ATTACH A COMPLETED REVIEW OF RESULTS PAGE FOR EACH FLOODING SOURCE.

Is the new hydrologic analysis being developed solely to revise the flow values presented in the FIS *(i.e. no changed hydraulic conditions)?* ☐ Yes ☒ No

If yes, does the 100-year water surface elevation change by 1.0 foot or more? ☐ Yes ☐ No

FEMA does not normally revise NFIP maps solely due to insignificant flow changes where changes in the 100-year water surface elevation are less than 1.0 foot.

5. HISTORICAL FLOODING INFORMATION

Is historical data available for the flooding source? ☐ Yes ☒ No

If yes, provide the following:

Location along flooding source: _____

Maximum peak discharge: _____ cfs

Second highest peak discharge: _____ cfs

Source of information: _____

6. GAGE RECORD INFORMATION

Location of the nearest gage to project site *(along flooding source or similar watershed: specify)*

N/A

Gaging Station: _____

Drainage area at gage: _____ mi^2

Number of years of data: _____

7. DATA REVISION

Please use the following table to list all the data and/or parameters affected by this request and identify them as new data *(New)* or as revising existing data *(Revised)*. *(If necessary, attach a separate sheet.)*

Data Parameter	New	Revised	Data Source
Basin Delineation	☐	☒	Changes due to development
Lag times	☐	☒	CCRFCD Criteria Manual
	☐	☐	
	☐	☐	
	☐	☐	

- Data source can be from Federal, State, or local government agency, or from a private source. Some State and local governments may have less strict data requirements than Federal Agencies, in which case the hydrologic data may not be accepted by FEMA unless it is demonstrated that the data give a better estimate of the flood discharge.

- Attach documentation corroborating each data source *(i.e. certified statement, report, bibliographical reference to a published document)*. In each case of a published document or a government report, providing copies of the cover and pertinent pages may be helpful.

8. METHODOLOGY FOR NEW ANALYSIS

☐ Statistical Analysis of Gage Records *(use Attachment A)*

☐ Regional Regression Equations *(use Attachment B)*

☒ Precipitation/Runoff Model *(use Attachment C)*

☐ Other *(specify; attach backup computations and supporting data)* _____

ATTACHMENT A: STATISTICAL ANALYSIS OF GAGE RECORDS

Gaging Station: _____

Gage Location (latitude and longitude): _____

	FIS:	Revised:
1. Number of years of data		
Systematic		
Historical		
2. Homogeneous data	☐ Yes ☐ No	☐ Yes ☐ No
3. Data adjustments	☐ Yes ☐ No	☐ Yes ☐ No
4. Number of high outliers		
Low outliers		
Zero events		
5. Generalized skew		
6. Station skew		
7. Adopted skew		
8. Probability distribution used (justify if log-Pearson III was not used)		
9. Transfer equations to ungaged sites		☐ Yes ☐ No
If yes, specify method		
10. Expected probability*	☐ Yes ☐ No	☐ Yes ☐ No
11. Comparison of results with other analyses	☐ Yes ☐ No	☐ Yes ☐ No
If yes, describe comparison		

*__FEMA__ does not accept expected probability analyses for the purpose of reflecting flood hazard information in a FIS.

If any data is not available, indicate by N/A

Attach analysis including plot of flood frequency curve.

ATTACHMENT B: REGIONAL REGRESSION EQUATIONS

1. Bibliographic Reference:

_____

_____

_____

(attach a copy of title page, table of contents, and pertinent pages including equations)

2. Gaged or ungaged stream: _____

3. Hydrologic region(s): _____
Attach backup map.

4. Provide parameters, values, and source of data used to define parameters.

_____

_____

_____

		FIS:	Revised:
5.	Urbanized conditions calculations	☐ Yes ☐ No	☐ Yes ☐ No
6.	Percent of watershed urbanization	_____	_____
7.	Is the watershed controlled?	☐ Yes ☐ No	☐ Yes ☐ No
8.	Comparison with other analyses	☐ Yes ☐ No	☐ Yes ☐ No

If the answer to 5, 7, or 8, is yes, explain methodology in comments.
If data is not available, indicate by N/A.

Comments

8.	Loss rate method:	SCS	SCS
	Source of soils information	SCS	SCS
	Source of land use information	1990 Aerial Photos	1995 Aerial Photos
9.	Channel routing method:	Muskingum	Muskingum
10.	Reservoir routing	☐ Yes ☒ No	☒ Yes ☐ No
11.	Baseflow considerations:	☐ Yes ☒ No	☐ Yes ☒ No
	If yes, explain how baseflow was determined:		
12.	Snowmelt considerations:	☐ Yes ☒ No	☐ Yes ☒ No
13.	Model calibration:	☐ Yes ☒ No	☐ Yes ☒ No
	If yes, explain how calibration was performed		
14.	Future land use condition:		☐ Yes ☒ No
	If yes, explain why		

NOTE: FEMA policy is to base flooding on existing conditions.
If data is not available, indicate by N/A.

Attach precipitation / runoff model, hydrologic model schematic, curve number calculations, time of concentration calculations, and supporting maps, delineating the watershed boundary and drainage area divides.

ATTACHMENT D: CONFIDENCE LIMITS EVALUATION

Stream: _____

Select one location for Confidence Limits Evaluation *(describe location)*: _____

_____

Discharge for selected location.

Exceedance Probability		FIS		Revised	
10%	(10-year)	_____	cfs	_____	cfs
2%	(50-year)	_____	cfs	_____	cfs
1%	(100-year)	_____	cfs	_____	cfs
0.2%	(500-year)	_____	cfs	_____	cfs

1% (100-year) Flood Confidence Intervals

90% Confidence Interval: 5% limit _____ *cfs*

95% limit _____

50% Confidence Interval: 25% limit _____

75% limit _____

If the value of the 100-year frequency flood in the FIS is beyond the 50% confidence interval but within the 90% confidence interval, does the 100-year water surface elevation change by 1.0 foot or more? ☐ Yes ☐ No

An example of confidence limits analysis can be found in Appendix 9 of Bulletin 17B.

Attach Confidence Limits Analysis.

FEDERAL EMERGENCY MANAGEMENT AGENCY **RIVERINE HYDRAULIC ANALYSIS FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 2.25 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

Community Name: **Clark County, Nevada and Incorporated Areas, City of North Las Vegas**

Flooding Source: **Range Wash**
(One form for each flooding source)

Project Name / Identifier: **Range Wash FIS Restudy**

1. REACH TO BE REVISED

Downstream limit: ***Confluence with Las Vegas Wash***
Upstream limit: **Elkhorn Road**

2. EFFECTIVE FIS

☐ Not studied

☒ Studied by approximate methods
Downstream limit of study: Confluence with Las Vegas Wash
Upstream limit of study: Elkhorn Road

☐ Studied by detailed methods
Downstream limit of study:
Upstream limit of study:

☐ Floodway delineated
Downstream limit of study:
Upstream limit of study:

3. HYDRAULIC ANALYSIS

Why is the hydraulic analysis different from that used to develop the FIRM. *(Check all that apply)*

☐ Not studied in FIS

☐ Improved hydrologic data / analysis. Explain: Basins have been delineated in more detail and reflect recent improvements by developers.

☐ Improved hydraulic analysis. Explain:

☒ Flood control structure. Explain: Range Wash Dike has been constructed, Confluence Detention Basin is under construction, Sloan Channel improvements have been constructed and are under construction.

☐ Other. Explain:

3. RIVERINE HYDRAULIC ANALYSIS FORM
Models Submitted

For areas which have detailed flooding:

Full input and output listings along with files on diskette (if available) for each of the models listed below (items 1, 2, 3, 4, and 5) and summary of the source of input parameters used in the models must be provided. The summary must include a complete description of any changes made from model to model (e.g. duplicate effective model to corrected effective model.) At a minimum, the Duplicate Effective (item 1) and the Revised or Post-Project Conditions (item 4) models must be submitted. See instructions for directions on when other models may be required.

For areas which do not have detailed flooding:

Only the 100-year flood profile is required. A hydraulic model is not required for areas which do not have detailed flooding; however, BFEs may not be added to the revised FIRM. If a hydraulic model is developed for the area, items 3 and 4 described below must be submitted.

If hydraulic models are not developed, hydraulic analyses for existing or pre-project conditions and revised or post-project conditions must be submitted. All calculations must be submitted for these analyses. (see item 6 below)

	Natural	Floodway
1. Duplicate Effective Model Copies of the hydraulic analysis used in the effective FIS, referred to as the effective models *(10-, 50-, 100-, and 500-year multi-profile runs and the floodway run)* must be obtained and then reproduced on the requestor's equipment to produce the duplicate effective model. This is required to assure that the effective model input data has been transferred correctly to the requestor's equipment and to assure that the revised data will be integrated into the effective data to provide a continuous FIS model upstream and downstream of the revised reach.	☐	☐
2. Corrected Effective Model The corrected effective model is the model that corrects any errors that occur in the duplicate effective model, adds any additional cross sections to the duplicate effective model, or incorporates more detailed topographic information than that used in the currently effective model. The corrected effective model must not reflect any man-made physical changes since the date of the effective model. An error could be a technical error in the modeling procedures, or any construction in the floodplain that occurred prior to the date of the effective model but was not incorporated into the effective model.	☐	☐
3. Existing or Pre-Project Conditions Model The duplicate effective or corrected model is modified to produce the existing or pre-project conditions model to reflect any modifications that have occurred within the floodplain since the date of the effective model but prior to the construction of the project for which the revision is being requested. If no modification has occurred since the date of the effective model, then this model would be identical to the corrected effective or duplicate effective model.	☐	☐
4. Revised or Post-Project Conditions Model The existing or pre-project conditions model *(or duplicate effective or corrected effective model, as appropriate)* is revised to reflect revised or post-project conditions. This model must incorporate any physical changes to the floodplain since the effective model was produced as well as the effects of the project. When the request is for proposed project this model should reflect proposed conditions.	☐	☐
5. Other: Please attach a sheet describing all other models submitted	Natural	Floodway
6. Hydraulic Analyses (Only if Hydraulic Models are not developed)	☒	☒

Please Attach all calculations for the existing or pre-project conditions and the revised or post-project conditions. *Proceed to form 5, "Riverine/Coastal Mapping Form".*

4. MODEL PARAMETERS (from model used to revise 100-year water surface elevation)

1. Discharges:

	Upstream limit	Downstream limit
10-year		
50-year		
100-year		
500-year		

Attach diagram showing changes in 100-year discharge

2. Explain how the starting water surface elevations were determined _____

3. Give range of friction loss coefficient *(Manning's "N")* Channel . . . . . _____

Overbanks . . . . . _____

If friction loss coefficients are different anywhere along the revised reach from those used to develop the FIRM, give location, value used in the effective FIS, and the revised values and an explanation as to how the revised values were determined.

Location	FIS	Revised

Explain: _____

4. Describe how the cross section geometry data were determined *(e.g., field survey, topographic map, taken from previous study)* and list cross sections that were added.

5. Were natural channel banks selected as the location of the left and right channel banks in the model?

☐ Yes ☐ No If no, explain why not: _____

4. MODEL PARAMETERS (Cont'd)

6. Explain how reach lengths for channel and overbanks were determined:

_____

_____

_____

_____

5. RESULTS (from model used to revise 100-year water surface elevations)

1. Do the results indicate:

   a. Water surface elevations higher than end points of cross sections? . . . . . ☐ Yes ☐ No

   b. Supercritical depth? . . . . . ☐ Yes ☐ No

   c. Critical depth? . . . . . ☐ Yes ☐ No

   d. Other unique situations . . . . . ☐ Yes ☐ No

   If yes to any of the above, attach an explanation that discusses the situation and how it is presented on the profiles, tables, and maps.

2. What is the maximum change in energy gradient between cross-sections? . . . . . _____
   Specify location . . . . . _____

3. What is the distance between the cross-sections in 2 above? . . . . . _____

4. What is the maximum distance between cross-sections? . . . . . _____
   Specify location . . . . . _____

5. Floodway determination
   a. What is the maximum surcharge allowed by the community or State? . . . . . _____ foot
   b. What is the maximum surcharge for the revised conditions? . . . . . _____ foot
   Specify location . . . . . _____
   c. What is the maximum velocity? . . . . . _____ fps
   Specify location . . . . . _____

   d. Are there any negative surcharge values at any cross-section ☐ Yes ☐ No
   If yes, the floodway may need to widen. If it is not widened, please explain and indicate the maximum negative surcharge.

Explain: _____

_____

_____

5. RESULTS (Cont'd)

6. Is the discharge value used to determine the floodway anywhere different from that used to determine the natural 100-year flood elevations? . . . . . ☐ Yes ☐ No
If yes, explain:

_____

_____

_____

7. Do 100-year water surface elevations increase at any location? . . . . . ☐ Yes ☐ No
If yes, please attach a list of the locations where the increases occur, state whether or not the increases are located on the requestor's property, and provide an explanation of the reason for the increases. *(For example: State if the increase is due to fill placed within the floodway fringe or placed within the currently adopted floodway limits)*

_____

_____

_____

Please attach a completed comparison table entitled: Water Surface Elevation Check (See page 6)

6. REVISED FIRM/FBFM AND FLOOD PROFILES

A. The revised water surface elevations tie into those computed by the effective FIS Model *(10-, 50-, 100-, and 500-year)* downstream of the project at cross-section _____ within _____ feet *(vertical)* and upstream of the project at cross section _____ within _____ feet *(vertical)*.

B. The revised floodway elevations tie into those computed by the effective FIS model, downstream of the project at cross section _____ within _____ feet *(vertical)* and upstream of the project at cross section _____ within _____ feet *(vertical)*.

C. Attach profiles, at the same vertical and horizontal scale as the profiles in the effective FIS report, showing stream bed and profiles of all floods studied (without encroachment). Also, label all cross sections, road crossings (including low chord an top-of-road data), culverts, tributaries, corporate limits, and study limits. If channel distance has changed, the stationing should be revised for all profile sheets.

D. Attach a Floodway Data Table showing data for each cross section listed in the published Floodway Data Table in the FIS report.

Proceed to Riverine / Coastal Mapping Form

FEDERAL EMERGENCY MANAGEMENT AGENCY **RIVERINE/COASTAL MAPPING FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 1.5 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

Community Name: **Clark County, Nevada and Incorporated Areas, City of North Las Vegas**

Flooding Source: **Range Wash**

Project Name / Identifier: **Range Wash FIS Restudy**

1. MAPPING CHANGES

1. A topographic work map of suitable scale, contour interval, and planimetric definition must be submitted showing *(indicate N/A when not applicable):*

		Included		
A.	Revised approximate 100-year floodplain boundaries (Zone A)	☒ Yes	☐ No	☐ N/A
B.	Revised detailed 100- and 500-year floodplain boundaries	☐ Yes	☐ No	☒ N/A
C.	Revised 100-year floodway boundaries	☐ Yes	☐ No	☒ N/A
D.	Location and alignment of all cross sections used in the revised hydraulic model with stationing control indicated	☒ Yes	☐ No	☐ N/A
E.	Stream alignments, road and dam alignments	☒ Yes	☐ No	☐ N/A
F.	Current community boundaries	☒ Yes	☐ No	☐ N/A
G.	Effective 100-~~and 500~~-year floodplain ~~and 100-year floodway~~ boundaries from the FIRM/~~FBFM~~ reduced or enlarged to the scale of the topographic work map	☒ Yes	☐ No	☐ N/A
H.	Tie-ins between the effective and revised 100- ~~and 500~~-year floodplains ~~and 100-year floodway~~ boundaries	☐ Yes	☐ No	☒ N/A
I.	The requestor's property boundaries and community easements	☐ Yes	☐ No	☒ N/A
J.	The signed certification of a registered professional engineer	☒ Yes	☐ No	☐ N/A
K.	Location and description of reference marks	☐ Yes	☐ No	☒ N/A
L.	Vertical datum (example: NGVD, NAVD etc.)	☒ Yes	☐ No	☐ N/A
M.	Coastal zone designations tie into adjacent areas not being revise	☐ Yes	☐ No	☒ N/A
N.	Location and alignment of all coastal transects used to revise the coastal analyses	☐ Yes	☐ No	☒ N/A

If any of the items above are marked no or N/A, please Explain:

Study includes the entire mapped reach of Range Wash by approximate methods no base flood elevations are determined.

2. What is the source and data of the updated topographic information *(example: orthophoto maps, July 1985; field survey, May 1979, beach profiles, June 1987, etc.)?* **Aerial Survey Topographic Mapping 3/15/95**

3. What is the scale and contour interval of the following work maps?

a. Effective FIS **1" = 400'** scale **4 ft** Contour interval

b. Revision Request **1" = 400'** scale **2 ft** Contour interval

NOTE: Revised topographic information must be of equal or greater detail.

4. Attach an annotated FIRM and FBFM at the scale of the effective FIRM and FBFM showing the revised 100-year and 500-year floodplains and the 100-year floodway boundaries and how they tie into those shown on the effective FIRM and FBFM downstream and upstream of the revision or adjacent to the area of revision for coastal studies.

Attach additional pages if needed.

1. MAPPING CHANGES (Cont'd)

5. Flood boundaries and 100-year water surface elevations:

Has the 100-year floodplain been shifted or increased or the 100-year water surface elevation increased at any location on the property other than the requestor's or community's? ☐ Yes ☒ No

If yes, please give the location of shift or increase and an explanation of the increase.

Shifted within community, due to more detailed and accurate topography

a. Have the affected property owners been notified of this shift or increase and the effect it will have on their property? . . . . . ☐ Yes ☒ No

If yes, please attach letters from these property owners stating they have no objections to the revised flood boundaries if a LOMR is being requested.

b. What is the number of insurable structures that will be impacted by this shift or increase? **none**

6. Have the floodway boundaries shifted or increased at any location compared to those shown on the effective FBFM or FIRM? . . . . . ☒ Yes ☐ No

If yes, explain:

Shifted within community, due to more detailed and accurate topography

7. If a V-zone has been designated, has it been delineated to extend landward to the heel of the primary frontal dune? ☐ Yes ☐ No

If no, explain:

8. Manual or digital map submission:

☒ Manual
☒ Digital

Digital map submissions may be used to update digital FIRMs (DFIRMs). For updating DFIRMs, these submissions must be coordinated with FEMA headquarters as far in advance of submission as possible.

2. EARTH FILL PLACEMENT

1. The fill is: ☒ Existing ☐ Proposed **Fill is associated with Cibola Project Case No. 95-09-1021C**

2. Has fill been / will be placed in the regulatory floodway? . . . . . ☐ Yes ☒ No
If yes, please attach complete Riverine Hydraulic Analysis Form.

3. Has fill been / will be placed in the floodway fringe *(area between the floodway and 100-year floodplain boundaries)?* . . . . . ☒ Yes ☐ No

A. Are fill slopes for granular materials steeper than one vertical on one-and-one-half horizontal? . . . . . ☐ Yes ☒ No

If yes, justify steeper slopes _____

B. Is adequate erosion protection provided for fill slopes exposed to moving flood waters? *(Slopes exposed to flows with velocities of up to 5 feet per second (fps) during the 100-year flood must, at a minimum, be protected by a cover of grass, vines, weeds, or similar vegetation; slopes exposed to flows with velocities greater than 5 fps during the 100-year flood must, at a minimum, be protected by stone or rock riprap.)* . . . . . ☒ Yes ☐ No

If no, describe erosion protection provided _____

C. Has all fill placed in revised 100-year floodplain been compacted to 95 percent of the maximum density obtainable with the Standard Proctor Test Method or acceptable equivalent method? ☒ Yes ☐ No

D. Can structures conceivably be constructed on the fill at any time in the future? ☒ Yes ☐ No

If yes, provide certification of fill compaction (item C. above) by the community's NFIP permit official, a registered professional engineer, or an accredited soils engineer.

4. Has fill been / will be placed in a V-zone? ☐ Yes ☒ No

If yes, is the fill protected from erosion by a flood control structure such as a revetment or seawall? ☐ Yes ☐ No

If yes, attach the coastal structures form.

FEDERAL EMERGENCY MANAGEMENT AGENCY **CHANNELIZATION FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 1.75 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

Community Name: **Clark County, Nevada and Incorporated Areas, City of North Las Vegas**

Flooding Source: **Range Wash**

Project Name / Identifier: **Range Wash FIS Restudy Channelization associated with Collins Buisness Park**

1. EXTENT OF CHANNELIZATION

Downstream limit: **Alexander Road**

Upstream limit: **Lamb Boulevard**

2. CHANNEL DESCRIPTION

1. Describe the inlet to the channel **3 - 9' x 6' RCB Culverts at Lamb Boulevard**

2. Briefly describe the shape of the channel *(both cross sectional and planimetric configuration)* and its lining *(channel bottom and sides)* **Concrete lined trapezoidal channel, 32 ft base width, 5.5 ft deep, 2:1 side slopes,**

3. Describe the outlet from the channel **4 - 12' x 7' RCB Culverts at Alexander Road**

4. The channelization includes:

- ☐ Levees *(Attach Levee Form)*
- ☐ Drop structures
- ☐ Superelevated sections
- ☒ Transitions in cross section geometry
- ☐ Debris basin/detention basin
- ☐ Energy Dissipater
- ☐ Other

5. Attach the following:

a. Certified engineering drawings showing channel alignment and locations of inlet, outlet, and items checked in item 4

b. Typical cross sections and profiles of channel banks and invert

3. HYDRAULIC CONSIDERATIONS

1. What is the 100-year discharge? . . . . . **2,140 used in model** cfs

2. Do the cross sections in the hydraulic model match the typical cross sections in the plans? ☒ Yes ☒ No

3. Are the channel banks higher than the 100-year flood elevations everywhere? . . . . . ☒ Yes ☐ No

4. Are the channel banks higher than the 100-year flood energy grade lines everywhere? . . . ☒ Yes ☐ No

5. Is the land on both sides of the channel above the adjacent 100-year flood elevation at all points along the channel? . . . . . ☒ Yes ☐ No

6. What is the range of freeboard . . . . . **1.5** --- **2.8** feet

7. What is the range of the 100-year flood velocities? . . . . . **10.7** --- **16.9** ft/sec

8. What is the lining type? (both bottom and sides) **Concrete**
   Explain how the channel lining prevents erosion and maintains channel stability *(attach documentation)*

9. What is the design elevation in the channel based on?

   ☐ Subcritical flow
   ☐ Critical flow
   ☒ Supercritical flow
   ☐ Energy grade line

   Is 100-year flood profiles based on the above type of flow? . . . . . ☐ Yes ☒ No

   If no, explain: Profiles included in the Collins Buisness Park Improvement Plans are based on the above types of flow. No base flood elevations are determined for this area.

10. Is there the potential for a hydraulic jump at the following locations?

    Inlet to the channel . . . . . ☐ Yes ☒ No
    Outlet of the channel . . . . . ☐ Yes ☒ No
    At Drop Structures . . . . . ☐ Yes ☒ No
    At Transitions . . . . . ☐ Yes ☒ No
    At other locations. Explain

    If the answer to any of the above is yes, please explain how the hydraulic jump is controlled and the effects of the hydraulic jump on the stability of the channel.

    Explain:

4. SEDIMENT TRANSPORT CONSIDERATIONS

1. A. Is there any indication from historical records that sediment transport (including scour and deposition) can affect the 100-year water surface elevations and/or the capacity of the channel? . . . . . ☐ Yes ☒ No

   B. Based on the conditions of the watershed and stream bed, is there a potential for sediment transport (including scour and deposition) to affect the 100-year water surface elevations and/or the capacity of the channel? . . . . . ☐ Yes ☒ No

2. If the answer to either 1A or 1B is yes:

   A. What is the estimated sediment (bed) load?
   _____ cfs (attach gradation curve)

   Explain method used to estimate load _____

   _____

   _____

   _____

   _____

   B. Is the 100-year flood velocity anywhere within the channel less than the 100-year flood velocity of the inlet? ☒ Yes ☐ No

   C. Will sediment accumulate anywhere within the channel? ☐ Yes ☒ No

   D. Will deposition or scour occur at or near the inlet? ☐ Yes ☒ No

   E. Will deposition or scour occur at or near the outlet? ☒ Yes ☐ No

Attach documentation showing affects on the hydrologic and hydraulic analyses

FEDERAL EMERGENCY MANAGEMENT AGENCY **CHANNELIZATION FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 1.75 hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Community Name: **Clark County, Nevada and Incorporated Areas, City of North Las Vegas**

Flooding Source: **Range Wash**

Project Name / Identifier: **Range Wash FIS Restudy Channelization associated with Sloan Channel**

1. EXTENT OF CHANNELIZATION

Downstream limit: **Stewart Avenue**

Upstream limit: **Owens Avenue**

2. CHANNEL DESCRIPTION

1. Describe the inlet to the channel
Continuation of Existing Concrete Channel

2. Briefly describe the shape of the channel *(both cross sectional and planimetric configuration)* and its lining *(channel bottom and sides)* **Concrete lined trapezoidal channel, 60 ft base width, 6.6 ft deep, 2:1 side slopes,**

3. Describe the outlet from the channel
8 - 10' x 3.5' RCB Culverts at Stewart Ave.

4. The channelization includes:

- ☐ Levees *(Attach Levee Form)*
- ☐ Drop structures
- ☐ Superelevated sections
- ☒ Transitions in cross section geometry
- ☐ Debris basin/detention basin
- ☐ Energy Dissipater
- ☐ Other

5. Attach the following:

a. Certified engineering drawings showing channel alignment and locations of inlet, outlet, and items checked in item 4

b. Typical cross sections and profiles of channel banks and invert

3. HYDRAULIC CONSIDERATIONS

1. What is the 100-year discharge? . . . . . **3,300 used in model** cfs

2. Do the cross sections in the hydraulic model match the typical cross sections in the plans? ☒ Yes ☒ No

3. Are the channel banks higher than the 100-year flood elevations everywhere? . . . . . ☒ Yes ☐ No

4. Are the channel banks higher than the 100-year flood energy grade lines everywhere? . . . ☒ Yes ☐ No

5. *Is the land on both sides of the channel above the adjacent 100-year flood elevation* at all points along the channel? . . . . . ☒ Yes ☐ No

6. What is the range of freeboard . . . . . **1.5** --- **'1.67** feet

7. What is the range of the 100-year flood velocities? . . . . . **7** --- **18** ft/sec

8. What is the lining type? (both bottom and sides) **Concrete**
   Explain how the channel lining prevents erosion and maintains channel stability *(attach documentation)*

9. What is the design elevation in the channel based on?

   ☒ Subcritical flow
   ☐ *Critical flow*
   ☒ Supercritical flow
   ☐ Energy grade line

   Is 100-year flood profiles based on the above type of flow? . . . . . ☐ Yes ☒ No

   If no, explain: Profiles included in the Sloan Channel Predesign Report are based on the above types of flow. No base flood elevations are determined for this area.

10. Is there the potential for a hydraulic jump at the following locations?

    Inlet to the channel . . . . . ☐ Yes ☒ No
    Outlet of the channel . . . . . ☐ Yes ☒ No
    At Drop Structures . . . . . ☒ Yes ☐ No
    At Transitions . . . . . ☐ Yes ☒ No
    At other locations. Explain

    If the answer to any of the above is yes, please explain how the hydraulic jump is controlled and the effects of the hydraulic jump on the stability of the channel.

    Explain: **Jumps are mild at upstream end of road crossing structures and are contained within the concrete channel section**

4. SEDIMENT TRANSPORT CONSIDERATIONS

1. A. Is there any indication from historical records that sediment transport (including scour and deposition) can affect the 100-year water surface elevations and/or the capacity of the channel? . . . . . ☐ Yes ☒ No

   B. Based on the conditions of the watershed and stream bed, is there a potential for sediment transport (including scour and deposition) to affect the 100-year water surface elevations and/or the capacity of the channel? . . . . . ☐ Yes ☒ No

2. If the answer to either 1A or 1B is yes:

   A. What is the estimated sediment (bed) load?
   _____ cfs (attach gradation curve)

   Explain method used to estimate load _____

   _____

   _____

   _____

   _____

   B. Is the 100-year flood velocity anywhere within the channel less than the 100-year flood velocity of the inlet? ☒ Yes ☐ No

   C. Will sediment accumulate anywhere within the channel? ☐ Yes ☒ No

   D. Will deposition or scour occur at or near the inlet? ☐ Yes ☒ No

   E. Will deposition or scour occur at or near the outlet? ☒ Yes ☐ No

Attach documentation showing affects on the hydrologic and hydraulic analyses

FEDERAL EMERGENCY MANAGEMENT AGENCY **LEVEE/FLOODWALL SYSTEM ANALYSES FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 3.0. hours per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

Community Name: Clark County, Nevada, and Incorporated Areas, City of North Las Vegas

Flooding Source: Range Wash

Project Name/Identifier: Range Wash FIS Restudy – West Range Wash Dike

REACH TO BE REVISED

Dike Downstream limit: North Las Vegas Detention Basin

Upstream limit: Ridge of Mountain-Las Vegas Range

This Levee/Floodwall analysis is based on:

- ☐ *upgrading of an existing levee/floodwall system*
- ☒ a newly constructed levee/floodwall system
- ☐ reanalysis of an existing levee/floodwall system

LEVEE/FLOODWALL SYSTEM ELEMENTS

1. Levee elements and locations are:

☒ earthen embankment, dike, berm etc.	Station 4+00	to 320+00
☐ structural floodwall	Station	to
☐ *other (describe)*	Station	to

Structural Type:

- ☐ monolithic cast-in place reinforced concrete
- ☐ reinforced concrete masonry block
- ☐ sheet piling
- ☐ other (describe)

2. Has this levee/floodwall system been certified by a Federal agency to provide protection against the 100-year flood event?

☐ Yes ☒ No

If yes, by which agency?

If yes, complete only the interior drainage section on pages 7 and 8 of this form and the operation and maintenance section of *Revision Requestor and Community Official Form.*

3. Attach certified drawings containing the following information (indicate drawing sheet numbers):

a. Plan of the levee embankment and floodwall structures. Sheet Numbers F-1, F-2 D-1 through D-10

b. A profile of the levee/floodwall system showing the 100-year water surface elevation, levee and/or wall crest and foundation, and closure locations for the total levee system. Sheet Numbers F-1, F-2 D-1 through D-10

c. A profile of the 100-year water surface elevation, closure opening outlet and inlet invert elevations, type and size of opening, and kind of closure device. Sheet Numbers N/A

d. A layout detail for the embankment protection measures. Sheet Numbers DT-1

e. Location, layout, and size and shape of the levee embankment features, foundation treatment, floodwall structure, closure structures, and pump stations. Sheet Numbers DT-1

FREEBOARD

1. The minimum freeboard provided above the 100-year water surface elevation is:

Riverine

3.0 feet or more at the downstream end and throughout	☒ Yes	☐ No
3.5 feet or more at the upstream end	☐ Yes	☐ No
4.0 feet immediately upstream of all structures and constrictions	☐ Yes	☐ No

Coastal

1.0 foot above the height of the one percent wave for the 100-year stillwater surge elevation or maximum wave runup (whichever is greater).	☐ Yes	☐ No
2.0 feet above 100-year stillwater surge elevation	☐ Yes	☐ No

Please note, occasionally exceptions are made to the minimum freeboard requirement. If an exception is requested, attach documentation addressing Part 65.10 (b) (1) (ii) of the National Flood Insurance Program regulations.

If no is answered to any of the above, please explain where and why: _____

2. Tabulate the elevations at critical locations (tabulate values at each levee crest grade change)

Station	Location	100-Year Water Surface Elevation	Levee Crest	Freeboard (ft.)
	Upper end			
		4.4' deep (typ)	15.3' high (typ)	10.9
See Water Surface Profiles - Section 5 - Sediment Transport Documentation Notebook				
	Lower end			

(Extend table on an added sheet as needed and reference)

SEDIMENT TRANSPORT CONSIDERATIONS

1. A. Is there any indication from historical records that sediment transport (including scour and deposition) can affect the 100-year water surface elevations?

☒ Yes ☐ No

B. Based on the conditions (such as geomorphology, vegetative cover and development of the watershed and stream bed, and bank conditions), is there a potential for debris and sediment transport (including scour and deposition) to affect the 100-year water surface elevations and/or the freeboard for the levee/floodwall?

☒ Yes ☐ No

2. If the answer to either 1A or 1B is yes:

A. What is the estimated sediment (bed material) load?

_____cfs (attach gradation curve) 2,670,000 Tons/day - peak

Explain method used to estimate the sediment transport and the depth of scour and/or deposition

See Section 5 - 3 Range Wash Sediment Transport Documentation Notebook

B. Will sediment accumulate anywhere along the levee/floodwall (such as along any bends in the channel)?

☒ Yes ☐ No

If yes, what is the minimum freeboard at these locations? 10.7 feet.

CLOSURES

1. Openings through the levee system:

☐ exist ☒ do not exist

If openings exist, list all closures:

Channel Station	Left or Right Bank	Opening Type	Highest Elevation for Opening Invert	Type of Closure Device

(Extend table on an added sheet as neded and reference)

Geotechnical and geologic data:

In addition to the required detail analysis reports, data obtained during field and laboratory investigations and used in the design analysis for the following levee system features should be submitted in a tabulated summary form. (Reference U.S. Army Corps of Engineers EM-1110-2-1906 Form 2086).

EMBANKMENT PROTECTION

1. The maximum levee slope landside is 3:1

2. The maximum levee slope floodside is 4:1

3. The range of *100-year riverine flood velocities along the levee?* 9 fps (min.)
   to 12 fps (max.)

4. Embankment material is protected by (describe the kind):
   Sediment Transport Equilibrium Analysis
   Dike base width ≈ 120' wide

5. Riprap Design Parameters: (Include references) ☐ Velocity; ☐ Tractive stress

Reach	Sideslope	Flow depth	Velocity	Curve or Straight	Stone Riprap D_{100}	D_{50}	Thickness	Depth of Toedown
Sta_____ to _____								
Sta_____ to _____								
Sta_____ to _____								

(Extend table on an added sheet as needed and reference)

6. Has a bedding/filter analysis and design been included ☐ Yes ☒ No

Describe the analysis used for other kinds of protection used (include copies of the design analysis):
see Sediment Transport Documentation Notebook in Section 5

Note: Attach engineering analysis to support construction plans.

1. Describe the basis for selection of critical location for analysis:
Dike has uniform cross-section

☐ Overall height: Sta_____, height 15.3 ft.

☐ Limiting foundation soil strength: See Geotechnical Investigation

Sta_____, depth_____to_____

strength Ø = _____degrees, c = _____psf

☐ slope: SS = 4 (h) to 1 (v)

(Repeat as needed on an added sheet for additional locations)

2. Specify the embankment stability analyses methodology used (e.g. circular arc, sliding block, infinite slope, etc.): SB-Slope, Version 3.0 program - Bishops simplified method of slices for circular failure surfaces

3. Summary of stability analysis results:

Case	Loading Conditions	Critical Safety Factor	Criteria (Min.)
I	End of construction	2.5	1.3
II	Sudden drawdown	1.8	1.0
III	Critical flood stage	1.7	1.4
IV	Steady seepage at flood stage	1.7	1.4
VI	Earthquake (Case I or III)	1.4	1.0

(Reference: U.S. Army Corps of Engineers EM-1110-2-1913 Table 6-1)

4. Was a seepage analysis for the embankment performed? ☐ Yes ☒ No

Describe methodology used:_____

5. Was a seepage analysis for the foundation performed? ☐ Yes ☒ No

Were uplift pressures at the embankment landside toe checked? ☐ Yes ☒ No

Were seepage exit gradients checked for piping potential? ☐ Yes ☒ No

6. The duration of 100-year flood hydrograph against the embankment is 8 Hrs.

Note: Attach engineering analysis to support construction plans.

1. Describe analysis submittal based on Code:

☐ UBC (1988) or ☐ Other (specify)_____

2. Stability analysis submitted provides for:
☐ Overturning; ☐ Sliding; If not, explain Top width of dike is 12' base width is approximately 120' - Stability not a problem - see Geotechnical Investigation

3. Loading included in the analyses were:

☐ Lateral earth @ P_A = _____psf; P_p = _____psf

☐ Surcharge--Slope @_____, ☐ surface_____psf

☐ Wind @ P_w = _____psf

☐ Seepage (Uplift); ☐ Earthquake @ P_{eq} = _____%g

☐ 100-year significant wave height_____ft.

☐ 100-year significant wave period_____sec.

4. Summary of Stability Analysis Results: Factors of Safety. Itemize for each range in site layout dimension and loading condition limitation for each respective reach.

Loading Condition	Criteria (Min) Overturn	Criteria (Min) Sliding	Sta_____ To_____ Overturn	Sta_____ To_____ Sliding	Sta_____ To_____ Overturn	Sta_____ To_____ Sliding
Dead & Wind	1.5	1.5				
Dead & Soil	1.5	1.5				
Dead, Soil, Flood & Impact	1.5	1.5				
Dead, Soil & Seismic	1.3	1.3				

(Ref: FEMA 114 Sept 1986; COE EM 1110-2-2502)

(Note: Extend table on an added sheet as needed and reference)

5. Foundation bearing strength for each soil type:

Bearing Pressure	Sustained Load	Short Term Load
Computed design maximum	_____psf	_____psf
Maximum allowable	_____psf	_____psf

6. Foundation scour protection ☐ is, ☐ is not provided, (describe)

_____

Note: Attach engineering analysis to support construction plans.

SETTLEMENT

1. Anticipated potential settlement has been determined and incorporated into the specified construction elevations to maintain the established freeboard margin.
   ☒ Yes ☐ No
2. The computed range of settlement is negligible ft. to _____ ft.
3. Settlement of the levee crest is determined to be primarily from:
   - ☐ Foundation consolidation
   - ☒ Embankment compression
   - ☐ Other (describe) _____
4. *Differential settlement of floodwalls*
   ☒ has ☐ has not been accommodated in the structural design and construction.

Note: Attach engineering analysis to support construction plans.

INTERIOR DRAINAGE – N/A

1. Specify size of each interior watershed
   - Draining to pressure conduit _____
   - Draining to ponding area _____
2. Relationships Established
   - *Ponding elevation vs. storage* ☐ Yes ☐ No
   - Ponding elevation vs. gravity flow ☐ Yes ☐ No
   - Differential head vs. gravity flow ☐ Yes ☐ No
3. The river flow duration curve is enclosed ☐ Yes ☐ No
4. Specify the discharge capacity of the head pressure conduit _____
5. Which Flooding Conditions Were Analyzed?
   - Gravity flow (Interior Watershed) ☐ Yes ☐ No
   - Common storm (River Watershed) ☐ Yes ☐ No
   - Historical ponding probability ☐ Yes ☐ No
   - Coastal wave overtopping ☐ Yes ☐ No

   If no, explain why: _____
6. Interior drainage has been analyzed based on joint probability of interior and exterior flooding and the capacities of pumping and outlet facilities to provide the established level of flood protection.
   ☐ Yes ☐ No

   If no, explain why: _____
7. The rate of seepage through the levee system for the 100-year flood is _____ cfs

1. The length of levee system used to drive this seepage rate is _____ ft.

2. Will a pumping plant(s) be used for interior drainage? ☐ Yes ☐ No

If yes, include the number of pumping plants: _____

For each pumping plant, list:	Plant #1	Plant #2
The number of pumps		
The ponding storage capacity		
The maximum pumping rate		
The maximum pumping head		
The pumping starting elevation		
The pumping stopping elevation		
Is the discharge facility protected?		
Is there a flood warning plan?		
How much time is available between warning and flooding?		

Will the operations be automatic? ☐ Yes ☐ No

If the pumps are electric, are there backup power sources? ☐ Yes ☐ No

(Reference: U.S. Army Corps of Engineers EM-1110-2-3101, 3102, 3103, 3104, and 3105)

Note: Include a copy of supporting documentation of data and analysis. Provide a map showing the flooded area and maximum ponding elevations for all interior watersheds that result in flooding.

OTHER DESIGN CRITERIA

1. The following items have been addressed as stated:

Liquifaction ☐ is ☒ is not a problem.
Hydrocompaction ☐ is ☒ is not a problem
Heave differential movement due to soils of high shrink/swell
☐ is ☒ is not a problem.

2. For each of these problems, state the basic facts and corrective action taken.

_____

_____

_____

_____

If the levee/floodwall is new or enlarged, will the structure adversely impact flood levels and/or flow velocities floodside of the structure?

☐ Yes ☐ No

Note: Attach supporting documentation

The planned/installed works are in full compliance with NFIP regulations, Section 44 CFR Ch. 1. 65.10

☒ Yes ☐ No

1. The operation plan incorporates all the provisions for closure devices as required in Section 65.10 (c) (1), of the NFIP regulations

N/A ☐ Yes ☐ No

2. The operation plan incorporates all the provisions for interior drainage as required in Section 65.10 (c) (2), of the NFIP regulations

N/A ☐ Yes ☐ No

If no to either of the above, please explain.

_____

FEDERAL EMERGENCY MANAGEMENT AGENCY **DAM FORM**	*O.M.B. Burden No. 3067-0148* *Expires July 31, 1997*	FEMA USE ONLY

PUBLIC BURDEN DISCLOSURE NOTICE

Public reporting burden for this form is estimated to average 0.5 hour per response. The burden estimate includes the time for reviewing instructions, searching existing data sources, gathering and maintaining the needed data, and completing and reviewing the form. Send comments regarding the accuracy of the burden estimate and any suggestions for reducing this burden, to: Information Collections Management, Federal Emergency Management Agency, 500 C Street, S.W., Washington, DC 20472; and to the Office of Management and Budget, Paperwork Reduction Project (3067-0148), Washington, DC 20503.

Community Name: Clark County, Nevada and Incorporated Areas, City of North Las Vegas

Flooding Source: Range Wash

Project Name/Identifier: Range Wash FIS Restudy - Range Wash/Sloan Channel Confluence Detention Basin

IDENTIFIER

Name of Dam: Range Wash/Sloan Channel Confluence Detention Basin

Location of dam along flood source (in terms of stream distance or cross section identifier):

5.5 miles upstream from Las Vegas Wash on the Range Wash

Check one of the following:

- ☐ Existing dam
- ☒ New dam
- ☐ Modifications of existing dam (describe modifications)_____

Was the dam designed by ____ Federal agency ____ State agency

For X Local government agency by X Private organization?

BACKGROUND

Does the dam have dedicated flood control storage? ☒ Yes ☐ No

Does the project involve revised hydrology? ☒ Yes ☐ No

If yes, complete Hydrologic Analysis Form and include calculations of the 100-year inflow flood hydrograph routed through the dam with the beginning pool at the normal pool elevation (spillway crest elevation for ungated spillway). Include any inflow hydrograph bulking by watershed sediment yield and provide necessary debris and sediment yield analysis.

Does the revised hydrology affect the 100-year water-surface elevation behind the dam or downstream of the dam? ☒ Yes ☐ No

If yes, complete the Riverine Hydraulic Analysis Form and complete the table shown on the following page.

	Stillwater Elevation Behind the Dam	
	FIS	Revised
10-year		
50-year		
100-year	N/A	1815.9
500-year		
Normal Pool Elevation		

Was long term sediment accumulation taken into consideration in determining the normal pool elevation? ☒ Yes ☐ No

Was the dam designed to withstand the hydrostatic and hydrodynamic forces associated with floods greater than the 100-year flood? ☒ Yes ☐ No

If no, and the dam has a reasonable probability of failure during the 100-year flood, please attach dam break analysis.

Provide the following data on the dam:

Height: 13.5' above ~~center~~ natural grade
Crest Elevation: 1821.5
100-year flood storage capacity: 1025 acre-ft
Freeboard (measured from 100-year water surface elevation): 5.6'

Spillway(s):

Type: ☐ gated ☒ ungated

Width: 2,200'
Height:
Crest Elevation: 1816.0

Outlet(s):

Type: ☐ gated ☒ ungated
2-LEVEL

	LOW	HIGH
Width:	5.6	114'
Height	4.0	
Diameter:		
Invert Elevation:	1798.8	1813.0

Explain flow regulation plan: Used for flood control) detention Normally empty.

Are the project features, including the emergency spillway, designed to accommodate the 100-year flood discharge without overtopping the dam? ☒ Yes ☐ No

Was the dam designed in accordance with all currently applicable local, State, and Federal regulations? ☒ Yes ☐ No

If no, please provide explanation.

FEMA may request a list of regulations that have been complied with and supporting documentation demonstrating compliance with these regulations.

Attach copy of formal operation and maintenance plan

Answer N/A to any questions which are not applicable

CONVERSATION WITH:	PROJECT INFORMATION:	
Kevin Eubanks	Communities:	Clark County City of North Las Vegas
Clark County Regional Flood Control District	State:	Nevada
	Study Contractor:	PBS&J
	Regional Project Officer:	Karl Mohr
	Tech. Eval. Contractor:	Michael Baker Jr., Inc.
	Flooding Source(s):	Range Wash

NOTES:

Kevin indicated the Cibola development project is applying for a LOMR. He requested we add to our documentation to accommodate the LOMR. The estimated flow in Sloan Channel being used in the LOMR was 5,500 cfs. He would like us to determine the flow at the Cibola site based on the West Range Wash Dike in place, but without the Confluence Detention Basin by modifying our hydrologic model. We should indicate in our documentation that the flow was determined for the interim condition impacting the Cibola site.

The Cibola case number is 95-09-1021C

Kelly Chuma	Communities:	Clark County City of North Las Vegas
City of North Las Vegas	State:	Nevada
	Study Contractor:	PBS&J
	Regional Project Officer:	Karl Mohr
	Tech. Eval. Contractor:	Michael Baker Jr., Inc.
	Flooding Source(s):	Range Wash

NOTES:

Indicated to Kelly that there is a large ponding area upstream of the I-15 culvert located near Walnut Road. If the stage storage relationship created by the ponding area and capacity of the culvert is considered it will reduce flow to eliminate the floodplain area in Walnut Road. If development fills the impoundment area the floodplain in Walnut would likely occur.

Kelly indicated she would check on this subject. It may not be good to remove the floodplain if development will eliminate the ponding.

She indicated City of North Las Vegas was not very concerned about Walnut Road and was more concerned about Vandenberg Drive. She believed it may be beneficial to determine base flood elevations along Vandenberg to make it easier for each small developer in the area.

657-2295	Flooding Source(s):	Range Wash

NOTES:

REGARDING: Schedule

Kelly requested that we call her while we are analyzing the Vandenberg area because that is an important and sensitive area for the CNLV.

Kelly would like a schedule of completion for this restudy.

Kelly asked if we had reviewed the Golden Triangle Industrial Park drainage study. It is a large industrial park on the west side of the UPRR extending to Craig Road. The study has higher flowrates than the DRAFT Range Wash FIS, and the CNLV has accepted those flows. The study was done by ALCA and is approximately 1 1/2 years old. Kelly said that she is lending the study to someone shortly, and she will call us when she gets it back, so that we may review it.

REGARDING: LOMRs and data used for the DFIRMs

Generally, records of LOMRs are the responsibility of the community. Michael Baker Jr. files LOMRs by their Case Number. They can provide us with LOMR information, but it may take a lot of research, which can get expensive.

Michael Baker Jr. can provide us with the hydraulic data. Once they receive a letter requesting the information, it can take about a week for someone to call us back with information on the time and cost needed to collect and send the data.

Flooding Source(s):	Range Wash

NOTES:

REGARDING: LOMRs and data used for the DFIRMs

Contact Tony Appleby at the project library with a request, in writing, to obtain LOMRs or hydrologic/hydraulic data used to update the DFIRMs.

For the DFIRM project, the majority of the hydraulic analyses were done by whoever generated the information on the effective FIRMs. Very little hydraulic analysis was done for the DFIRMs. Two areas with new hydraulics include the Tropicana restudy, and a letter giving the best available data for the Las Vegas Wash near the Interstate. CCRFCD has done some revisions, and individual LOMRs have been included.

A revised FIS text gives information on references used for the new DFIRMs. The revised text is available from the Map Distribution Center, 1-800-358-9616.

NOTES:

REGARDING: Sloan Channel

- The portion of the Sloan Channel between Owens and Stewart is essentially done.
- The next portion for construction is between Stewart and Charleston. He estimates that the channel may be complete in about a year.
- The next phase for construction is between Charleston and the Las Vegas Wash. He does not know when construction will begin on this phase.

Mike Hand is the project coordinator at Clark County Public Works.

GCW is currently working on some of the Sloan Channel drawings. The set that the County has is a 90% complete set. The profile on the first sheet of that set is not quite right (the slope is right, but an elevation is not), so it will be fixed on the new drawings that will be plotted by GCW next week. Noel said he can get a copy of the new drawings to PBS&J when they are finished.

Noel can get us a disk copy of the HEC-2 model. He said that one cross-section has changed since that HEC-2 model was done, and that change may not be in the HEC-2 model.

GCW obtained a CLOMR on the Las Vegas Wash through the Desert Rose Golf Course. They also did a LOMR for the Sloan Channel from Charleston to Vegas Valley. I looked at the DFIRM, Map 32003C 2200 D, and it appears that the map does include those LOMRs.

GCW did the Stonebridge and Collage developments.

Flooding Source(s):	Range Wash

NOTES:

REGARDING: Data Collection

Regarding the aerial topography project currently in progress for the CNLV Corporate Boundaries, Kelly investigated the possibility of making the topography in the Range Wash study area available prior to the topography project completion date; however they are not able to expedite the panels in the Range Wash area, so the new topography will not be available until September or October.

CNLV is searching for the technical documentation on the effective FIRMS.

Kelly will loan PBS&J a copy of the *Western and Eastern Tributaries of Range Wash Flood Control Facility Plan*, by Boyle, dated 1991.

Kelly found some flooding photos showing damage in the Vandenberg area.

Kelly will obtain copies of the CNLV, 1981 topography sheets 4 and 5. If we need other plans, or any other topography, Marshall Hill is the person to contact at 657-2270.

To obtain As-built certifications, Steve Combs, the chief inspector, is the person to contact at 642-1827. PBS&J will provide him with a list of certifications needed. (Kelly does have some of the As-built certifications that we will need.)

NOTES:

REGARDING: ***Transbasin Diversion Hydrologic Evaluation***

The *Transbasin Diversion Hydrologic Evaluation* is a technical report that Black & Veatch did several years ago for the City of North Las Vegas. Its purpose was to determine whether the North Las Vegas Detention Basin could accept flow from the Range Wash Diversion Dike without being modified. The report also addressed an omission between hydrologic analyses prepared for the Range Wash by Boyle, and the *Flood Control Facilities Plan for the Northern Las Vegas Wash*, by Black & Veatch. The report is between five and seven pages, but 10 to 15 different storm centerings were developed to account for a variety of conditions and the lapse in analyses between the two firms. The *North Las Vegas Detention Basin Outlet Modification Report* covers the most intense storms, and has a small amount of reanalysis.

CCRFCD will provide PBS&J with a copy of the *Transbasin Diversion Hydrologic Evaluation* if it can be located.

HYDRAULICS AND FLOODPLAIN DELINEATIONS

- Don Davis explained the hydraulic analysis performed for the FIS and presented the Work Maps and flood hazard boundary delineations. The City of North Las Vegas, Clark County, and the CCRFCD will review the final submittal prior to PBS&J submitting to FEMA.

- Kevin mentioned that FEMA's criteria to end the flood hazard delineation on drainage areas less than one square mile and widths less than 20 feet may not apply to restudies with mapped flood hazard areas. It was agreed that the delineation in the study would be submitted according to this criteria.

- Don discussed the limits of the flood plain delineations by reach through the study area.

- Don explained flows in Walnut Road are presently reduced due to the culvert capacity at the I-15 crossing and the large ponding area upstream. The situation may change with development, and a larger flow may be directed toward Walnut.

- Randy Tarr would prefer that the area near I-15 and Walnut Road remain A Zone for regulatory purposes since no structures are effected. Randy is concerned that the area of surface detention north of I-15 will be filled in. If the removal of the downstream reach from the A Zone is dependent on the surface detention and I-15 culvert restriction, then North Las Vegas prefers that Walnut remain A Zone. Don will evaluate the floodplain delineation based on removal of the storage capacity and unrestricted flows.

- At Vandenburg 970 cfs goes over the culvert and 500 cfs goes through the culvert. The overflow spill does not appear to return to the channel until after it crosses Craig Road.

- In the main reach of the wash, the flows are confined to channel limits. Kevin would like the proposed and DFIRM 95 delineation maps on diskette to FEMA with the submittal.

- Kelly Chuma's request to develop elevations on Vandenburg Channel was discussed. It was generally felt that the current analysis would suffice for flood plain management purposes.

- On the downstream reach, Don explained the difference in the DFIRM 95 and the proposed delineation. Steve mentioned that the Cybola Channel has been revised. Don mentioned that impact of the Charleston Avenue improvements on the DFIRM 95 delineations.

- The Technical Support Data Notebook and the full documentation will be sent to Steve, Kevin, and Randy. Kevin suggested that one more meeting be held to review the submittal prior to submitting to FEMA.

NEXT MEETING DATE

- Tuesday, February 20, 1996 @ 9:00 A.M. at CCRFCD.

MEETING MINUTES

PROJECT: Range Wash FIS Restudy
PBS&J Reference No. 51804.00

DATE: December 12, 1995

TIME: 9:00 a.m.

LOCATION: CCRFCD

SUBJECT: December Progress Meeting

ATTENDEES:

Kevin Eubanks, P.E.	CCRFCD
Randy Tarr, P.E.	CNLV
William Brandt, P.E.	CCPW
Steve Parrish, E.I.T.	CCPW
Virginia Valentine, P.E.	PBS&J
Don Davis, P.E.	PBS&J

SUMMARY OF DISCUSSION ON HYDROLOGY

The basin delineation upstream of the Vandenberg Channel was clarified. CNLV had inquired about a basin boundary located at the beginning of the channel. Two basins add together at this location. The separate basins pass under the railroad tracks at two separate locations upstream. The hydrologic model and delineation on the map are correct, however the node labels were labeled incorrectly on the map. The node labels for G1, F3, and F4, on the Hydrologic Subbasins Map (Figure 5B) will be revised.

The regulatory discharge, established by the previous FIS, at the Vandenberg Channel is 1,800 cfs. The flow from the PBS&J model is 1470 cfs. The PBS&J model subdivides the basin used in the FIS, such that portions of the flow go to Walnut Road and a swale along the railroad spur. If the flows to Walnut Road and the railroad spur are combined with the flow to the channel, the flow is approximately 1,800 cfs, corresponding very well to the previous FIS model.

The Lag times for basins less than one square mile were reviewed and revised. Two methods were used instead of the SCS NEH-4 Slope-Velocity Curve. For smaller basins, the average travel time velocity was estimated using the equations adopted by FEMA for a multiple channel flow regime used in alluvial fan analysis. When the basin size was approximately one square mile (greater than .75 square miles), the USBR Lag Equation was used. The average velocity was determined based on the time of concentration and the length of the water course. The revisions increased the travel time velocities for the smaller basins, but had little impact on the overall hydrologic analysis. The peak flows at key locations remained approximately the same. Tables summarizing revised velocity and Lag calculations and the revised table of Hydrologic Results are enclosed.

PBS&J

In the previous meeting it was noted that higher flows had been used at Walnut Road and the railroad spur. After reviewing the previous studies, Kelly Chuma informed PBS&J, the higher flows were not based on a hydrologic analysis, but were based on upstream culvert capacities. The developers had based there design on the maximum flow which could reach their site through culverts under Interstate 15. The flows from the PBS&J model were acceptable.

SUMMARY OF DISCUSSION ON TOPOGRAPHIC MAPPING

PBS&J received a large portion of the CNLV Topographic Mapping on December 11, 1995.

The remaining applicable area should be available during the week.

SUMMARY OF DISCUSSION ON FLOODPLAIN DELINEATION

The A Flood Zone delineation along the Vandenberg Channel will probably not change significantly. PBS&J will make preliminary evaluations to determine if a detailed hydraulic evaluation of the channel would be beneficial, and if it could be done within the present budget. Randy Tarr will provide the design plans for the road and channel to establish cross-sections. The topographic mapping may be used for slopes. Randy Tarr indicated the main issue was the flow developers should use as a basis for design.

The A Zone near the railroad spur will remain even though the tributary drainage area is less than one square mile. It will remain since it is a ponding area, and already mapped as an A Zone.

The A Zone which follows Walnut Road , Wendy Lane, Alexander Road, Lamb Boulevard and Faberge Avenue, will likely be eliminated due to a channel collecting flow along Craig Road and flows within the street less than one foot deep.

The A Zone in Bonanza Road will likely be eliminated due to a dike diverting most of the upstream flow. The dike has already been accepted by FEMA and is included in the DFIRMs.

The A Zone along the east side of Sloan Channel between Stewart Avenue and Charleston Boulevard will be eliminated based on the reduced flow due to the Confluence Detention Basin.

CCRFCD indicated Sloan Channel will soon be improved between Stewart and Charleston. If the A Zone cannot be eliminated based on the existing channel, the channel improvements may be included to obtain a CLOMR.

The Cibola/Magnolia Estates development is improving in the A Zone west of the channel and south of Stewart Avenue. Steve Parrish will provide a grading plan for the development.

MEETING MINUTES

SCHEDULE

A revised schedule is enclosed. The acquisition of topographic mapping has delayed the draft report submittal date approximately two weeks.

The draft report will be submitted at the next progress meeting.

The next progress meeting was scheduled for January 23, 1995, at 9:00 a.m., at the CCRFCD office.

SELECTION CRITERIA:

USBR Equation used for basins larger thna 1 sq. mile; Use also for basin approximately 1 sq. mile - basins greater than .75 sq. miles

FEMA multiple channel equation accounts for slope and roughness coefficient. Dawdy equation assumes critical flow. Use FEMA equation for basins less than .75 sq. miles. Subbasin flow is typically shallow with multiple collectors and subcritical.

RANGE WASH FLOOD INSURANCE
RESTUDY
PROJECT TIME SCHEDULE

Sheet 1 of 1

POST, BUCKLEY, SCHUH & JERNIGAN, INC.

MEETING MINUTES

PROJECT: Range Wash FIS Restudy
PBS&J Reference No. 51804.00

DATE: November 9, 1995

TIME: 10:00 a.m.

LOCATION: CCRFCD

SUBJECT: November Progress Meeting

ATTENDEES:

Kevin Eubanks, P.E.	CCRFCD
Randy Tarr, P.E.	CNLV
Kelly Chuma, P.E.	CNLV
William Brandt, P.E.	CCPW
Steve Parrish, E.I.T.	CCPW
Virginia Valentine, P.E.	PBS&J
Don Davis, P.E.	PBS&J
Kathy Kingston, P.E.	PBS&J

SUMMARY OF DISCUSSION ON HYDROLOGY

- The hydrologic results were reviewed with flows shown on the JMM topographic maps.
- The node labels for G1, F3, and F4 on the Hydrologic Subbasins Map (Figure 5B) were shown at incorrect locations and will be revised.
- The flow to the upstream end of the Vandenberg Channel was 1,470 cfs. This value differs from the value currently accepted by the City of North Las Vegas (CNLV), which is 1,800 cfs. The difference may be attributable to the Lag time calculations. CNLV noted velocities from the SCS NEH-4 Slope-Velocity Curve (CCRFCD Manual Figure 602) are only to be used for preliminary analysis.
- Flows near the Walnut Industrial Park were also lower than previous studies. This study indicated two flows of 180 cfs each. Previous study had flows of 350 or 450 cfs.
- CNLV has been threatened with lawsuits regarding the Vandenberg Channel. It will be important to explain or resolve discrepancies from previous studies.

SUMMARY OF DISCUSSION ON TOPOGRAPHIC MAPPING

- CNLV Topographic Mapping Project is expected to be completed in early January.
- CNLV will fax a copy of the map coverage to PBS&J.

PBS&J

- Portions of the mapping project may be completed earlier. PBS&J and CNLV will coordinate to identify what sections of the mapping project should be expedited.

SUMMARY OF DISCUSSION ON FLOODPLAIN DELINEATION

- The Vandenberg Channel has a capacity of approximately 550 cfs. The flow of 1,470 would overtop the banks of the Channel. Even though the flow is less, the limits of flooding will probably not be significantly different from indicated on the current FEMA map. The area should be included in the Study based on a different flow rate, even if the limits of flooding are similar.

- The Flood Zone upstream of the Railroad near the Walnut Industrial Park has tributary areas less than one square mile and will be eliminated.

- The Flood Zone north of the Railroad tributary to Vandenberg Channel will be revised. The present Flood Zone is not associated with the major flow to this location.

- Flood Zone near Alexander is expected to be revised.

- Sloan Channel has apparent capacity to convey the flows.

- The area near Stewart may require special attention. There is a proposed development in the area called Magnolia Estates or Cibola. PBS&J will obtain the drainage study for the development.

- PBS&J transmitted a letter requesting additional services to do cross-section surveys.

SCHEDULE

- The schedule is on track for a January submittal of the draft document.

NEXT MEETING DATE

- The next progress meeting was scheduled for Tuesday, December 12, 9:00 a.m., at the CCRFCD office.

jj

Distribution: Attendees
Robert Thompson, P.E. CCPW

MEETING MINUTES

PROJECT: Range Wash FIS Restudy
PBS&J Reference No. 51804.00

DATE: October 5, 1995

TIME: 10:00 a.m.

LOCATION: CCRFCD

SUBJECT: October Progress Meeting

ATTENDEES:

Kevin Eubanks, P.E.	CCRFCD
William Brandt, P.E.	CCPW
Steve Parrish, E.I.T.	CCPW
Virginia Valentine, P.E.	PBS&J
Don Davis, P.E.	PBS&J
Kathy Kingston, P.E.	PBS&J

STATUS AND RESULTS OF HYDROLOGIC MODELING

- PBS&J will set up a meeting to present hydrology to CNLV.
- PBS&J used the Orchards hydrology as a basis for modeling the lower portion of the watershed. A small detention basin included in the Orchards model was excluded from this FIS model. Clark County said that the detention basin was a temporary basin for construction and that the Orchards channel was designed to handle the flow without it. There is another study on facilities for the Orchards development without the detention basin.
- The hydrologic results are close to the previous hydrology until the Orchards basins are used and flow rates are increased. The difference is mainly due to use of higher rainfall for that area.
- The design hydrology for the Confluence Detention Basin is part of the submittal to FEMA, so any differences in the models need to be explained.
- The PBS&J modeling shows that more intense storms centered downstream of the Confluence Detention Basin produce higher flow rates in the Sloan Channel than a storm over the entire watershed. The storm distribution has a significant impact on the flow values. The PBS&J models show a decrease in peak flow from the upstream Node V1 to the downstream Node V2 due to the storm distribution changing from SDN 3 to SDN 5.

- Clark County is concerned with the portion of the Sloan Channel that is currently under design and being considered to remain unlined. The County needs to know of any changes in design flow as soon as possible. Mike Hand is the Project Manager.

- Clark County has plans for the diversion channel for Hollywood Park, at the Northeast corner of Bonanza and Sloan.

- The hydrology report will be completed next week.

COMMENTS ON DATA COLLECTION REPORT

- No comments from CCRFCD or Clark County.

- PBS&J will check for comments by CNLV.

SURVEY CONTROL

PBS&J will contact CNLV to determine when their topography will be ready. At this time, it appears that the CNLV topography will be too late to allow proceeding without delay to the project schedule. PBS&J would like authorization to do fieldwork in key places where cross-sections are needed. Even if the CNLV topography is ready in time, cross-sections along the Sloan Channel may be needed. PBS&J will provide a letter giving a clear proposal on the work needed with a request for authorization of additional funds.

NEXT MEETING DATE

Thursday, November 9, 10:00 a.m., at CCRFCD.

SUMMARY OF DISCUSSION

I. SUBMITTALS

- PBS&J presented a Project Control Plan showing submittal dates, project personnel, budget, quality control plan, schedule, notice to proceed, and a copy of the contract.
- The hydrologic analysis will be submitted on October 2.

901 North Green Valley Parkway Las Vegas, Nevada 89014 Telephone : (702) 263-7275 Fax : (702) 263-7200

II. DATA COLLECTION/RESEARCH

- The photo documentation of the field visit is nearing completion.
- PBS&J will use the hydrology from the Confluence Detention Basin, with any necessary modifications such as storm centering and basin subdividing.
- PBS&J has collected channel plans for the majority of the improved Range Wash/Sloan Channel.
- PBS&J will call CNLV to search for the Vandenberg Channel Plans.
- PBS&J has collected several HEC-2 models for portions of the Sloan Channel.
- For the majority of the Range Wash upstream of Las Vegas Boulevard, PBS&J is planning to use the CNLV 2-foot contour topography that is currently being prepared and is expected to be complete within two months. The topography will be available in a digital GIS format.
- A drainage study has recently been prepared for a manufacturing site between Lone Mountain Road and Interstate 15, an area that is near the Range Wash. PBS&J will search for that drainage study.
- CCPW did maintenance for the portion of the Sloan Channel between Owens and Lake Mead. An invert may have been changed. PBS&J will contact Cheri Reeves at CCPW.

III. PROJECT SCOPE

- CCRFCD only wants this FIS to concentrate on those areas shown in Flood Zone A on the newly effective DFIRMs. The only documentation needed for submittal is that needed to change the Flood Zones.

IV. ENTITY COORDINATION

- Next Meeting: Thursday, October 5, 10:00 a.m., at CCRFCD.

SUMMARY OF DISCUSSION

Available Topography

- The CNLV Resources Division expects to have new aerial topography completed in two months. CNLV is to investigate making the portion of the topography near the Range Wash available sooner.

- Bill Brandt will search for sheets 44 and 45 of the FIS topography, dated 1984.

Available Hydrologic/Hydraulic Data

- Obtain a copy of the LOMR for Winterwood prepared by GCW.
- Contact Dennis Perry at Clark County to obtain copies of drainage studies for the recent developments near the Sloan Channel.
- Obtain Lewis Homes Peachtree data on bank protection for the Sloan Channel, by GCW.
- Obtain from CNLV, Western & Eastern Tributaries of Range Wash Flood Control Facility Plan (Boyle, 1991).
- Transbasin Diversion Hydrologic Evaluation may be available from Black & Veatch.
- "As-builts" for the Confluence Detention Basin will not be available by the time of submittal and will require a CLOMR.

Flood Hazard Data

- If that information may be useful, contact the repository at Michael Baker Jr. If there is a fee for this information, CCRFCD may be able to get the fee waived.

- CNLV and Clark County have some of that data.

Flooding

- Flooding occurred along Sloan Channel in 1984.
- The Vandenberg channel has had frequent flooding problems.
- Stonegate had recent flooding problems.
- Where the channel curves near Carey, water overtopped it and flooded a mobile home park.
- CNLV will investigate availability of flooding photographs.
- PBS&J may search CCRFCD photograph files.

GIS data

- PBS&J may use the recent GIS orthophotos to prepare base maps, but may use 1984 FIS topography for contours or more recent topography, rather than use the digital topography with 10-ft contour intervals.

- CCRFCD has an interlocal with GISMO, so the GIS information will have no fee for this project. PBS&J will draft a data request letter for Kevin Eubanks to sign.

Data for Range Wash Dike

- A copy of the CCRFCD Operations and Maintenance Manual and the Maintenance Work Program will be sent to FEMA.

- As-built certifications can be obtained from Steve Combs or Kelly Chuma at the CNLV.

Hydrology/Hydraulics

- CCRFCD indicated HEC-1 modeling based on Confluence Detention Basin models will be acceptable hydrology.

Project Schedule

- Attached.

Next Meeting

- August 24, 10:00 a.m., at CCRFCD.

Range Wash Flood Insurance Study
PBS&J # 51804.00

Dear Don:

I am writing in response to your request dated November 9, 1995, for $10,000 from the supplemental services portion of the contract to perform surveying services. During the November progress meeting we discussed the possibility of using new topographic mapping being developed by the City of North Las Vegas. The mapping for the study area will be available on December 8, 1995, according to Mr. Randy Tarr, Administrator of Development and Flood Control for the City of North Las Vegas. It is my recommendation to wait until the topography is ready and then reassess your surveying needs to complete the study. At that time you may resubmit a revised request if necessary.

If you should have any further questions, please feel free to call.

RE: RANGE WASH FLOOD INSURANCE STUDY RESTUDY

Dear Kevin:

Post, Buckley, Schuh & Jernigan, Inc. (PBS&J) is requesting an amount of ten thousand dollars *($10,000.00) from the supplemental services portion of our contract to perform surveying services.*

Topography with 2-foot contour interval, from the City of North Las Vegas, has not yet become available. It is not expected to be available until January.

The survey services would include surveyed cross-sections to perform normal depth calculations. The Montgomery 1984 topography could be used as a base map, supplemented by surveyed cross-sections in sufficient locations to determine depth and width of floodplain.

Sincerely,

Post, Buckley, Schuh & Jernigan, Inc.

Donald W. Davis, P.E.
Project Manager

Range Wash Flood Insurance Study
PBS&J # 51804.00

Dear Don,

A review of the Draft Hydrology Study for the Range Wash Flood Insurance Restudy has been completed. The methods, format and results of the study were found acceptable to the District. Subsequent to addressing any comments that may be offered at our next progress meeting on November 9, 1995, PBS&J should continue on to the hydraulics component of the study.

Thank you for the timely submittal of this study. If you should have any further questions, please feel free to call.

RE: RANGE WASH FLOOD INSURANCE RESTUDY, CLARK COUNTY, NEVADA
PBS&J REFERENCE NO: 51804.00

Dear Mr. Appleby:

Post, Buckley, Schuh & Jernigan, Inc. (PBS&J), under contract with the Clark County Regional Flood Control District (CCRFCD), is preparing a Flood Insurance Restudy of the Range Wash, located in the City of North Las Vegas, and Clark County, Nevada. In particular areas we need the hydrologic and/or hydraulic data that was used to create the DFIRMs. The enclosed figures indicate the areas for which we need information from your project library.

Figure 4 is a copy of the DFIRM, Map Number 32003 C 2200 D, Clark County and Incorporated Areas, effective date August 16, 1995, that shows one of our areas of interest. Figure A is a copy of the older FIRMs, Maps Number 320003 1025B and 320003 1250B, Clark County, Nevada, effective date September 29, 1989. As the Flood Zone A in Figure 4 is similar to the Flood Zone A in Figure A in the area surrounded by Owens Ave., Beesley Dr., Charleston Blvd., and North Linn Ln., the information we need may be from the recently superseded Flood Insurance Study from 1989. Figure 3 is a copy of the DFIRMs, Map Numbers 32003C 1790D, 32003C 2180D and 32003C 2176D, Clark County and Incorporated Areas, effective date August 16, 1995, that shows our other area of interest.

Please call me with an estimate of the time and cost needed to collect and send us this information. Should you have any questions please feel free to call me, or Kathleen Kingston of our office, at (702) 263-7275.

Sincerely,

Post, Buckley, Schuh & Jernigan, Inc.

Re: J-398; West Range Wash Diversion Dike

Dear Mr. Combs:

Thank you for the set of as-builts, compaction results and soil cement reports. The only discrepancy I found with the reports was that Section 2615 of the specifications state that the soil cement should have a 600 psi strength at 7 days. The soil cement reports submitted state 600 psi at 28 days. Most of the samples did in fact meet the 600 psi at 7 days but there were a couple that didn't. I don't believe this to be a problem, however I would like some clarification to the specification.

This letter is authorization to divert and impound flood waters behind the newly constructed embankments as mentioned above. The impoundment is only for short term only as the design provides for transport of flood waters to a detention facility and is not intended to behave like a storage impoundment.

A minimum of two (2) feet of freeboard shall be maintained at all times. The freeboard shall be measured from water surface to the crest. The structure should be periodically inspected for slumps, cracks, seepage, differential settlement and other deleterious conditions. This is particularly applicable after severe storms and significant seismic events.

FILE COPY

If you have any questions concerning this matter, please contact me at your earliest convenience.

Sincerely,

Jason King, P.E.

RE: J-398; WEST RANGE WASH DIVERSION DIKE

Dear Mr. King:

I am in receipt of your letter dated November 7, 1994. You are correct that Section 02615 of the specifications state that the soil cement should have a 600 P.S.I. strength at 7 days. Two samples were sightly below the required 600 P.S.I. at 7 days. One tested on 2/14/94 broke at 560 P.S.I. at 7 days, the second tested on 2/15/94 broke at 550 P.S.I. at 7 days.

A core taken at Station 22 + 00 (soil cement placed on the same day as the cylinder tested on 2/15/94) obtained a strength of 820 P.S.I. at 28 days. In our opinion, the soil cement will perform as intended.

The structure shall be inspected by City of North Las Vegas personnel periodically and after severe storms or significant seismic events.

If you have any questions concerning this matter please do not hesitate to contact me at (702) 642-1827.

Sincerely,

Stephen A. Combs
Chief Construction Inspector

Converse Consultants Southwest, Inc.

Consulting Engineering and Applied Sciences

August 2, 1994

92-33377-01

City of North Las Vegas
151 West Brooks Avenue, Suite F
North Las Vegas, NV 89036

Attention: Mr. Gil Gilpin

Subject: Final Grading Report
West Range Wash Diversion Dike
North Las Vegas, Nevada

Gentlemen:

INTRODUCTION

This is to report the results of tests and observations made during the construction for the subject project. The intent of this report is to provide documentation of testing services to show that the field work as described below was performed in accordance with our recommendations.

- Our observation and testing for the period between January 3, 1994 and April 27, 1994
- The foundation materials covered by this report include the area of the structure footprint and approximately 5 feet outside the structure footprint.

The following plans, specifications and reports were used as our guideline and reference on this project:

- Soil and Foundation Investigation report for the subject project, dated January 8, 1992, (Converse Project No. 91-33298-01)
- Soil Cement Mix Designs report for the subject project, dated January 7, 1992, (Converse Project No. 91-33421-01)

SCOPE OF SERVICES

Our services were performed in accordance with your authorization dated July 29, 1991.

Converse Consultants Southwest, Inc.
4670 South Polaris Avenue
Las Vegas, Nevada 89103-5615
Telephone (702) 795-2121
Facsimile (702) 798-0098

Periodic tests and observations were provided by a representative of Converse Consultants Southwest, Inc. (Converse) to monitor the grading contractor for substantial compliance with the drawings and job requirements. The presence of our field representative at the site was to provide to the owner a source of professional advice, opinions and recommendations based upon the field representative's observations of the contractor's work, and did not include any superintending, supervision or direction of the actual work of the contractor or the contractor's workmen.

Field density tests were made during grading to determine the degree of compaction and moisture content. Where tests or field observations indicated insufficient density, additional compaction, with adjustment of the moisture content where necessary, was performed before the next layer was added.

Bulk samples of representative soil types were taken to our laboratory during grading for determination of maximum density-optimum moisture.

Two soil cement mix designs were performed in accordance with our proposal dated July 29, 1991. Soil cement used for the purpose of erosion protection was sampled during the project and brought to the lab in order to determine if minimum compressive strengths were being achieved in the field.

A slope stability analysis was performed in order to determine the minimum factor of safety for the dike and is part of the original Geotechnical Investigation, dated January 8, 1992 (Converse Project No. 91-33298-01). An additional Slope Stability Analysis was performed June 22, 1992 (Converse Project No. 91-33298-02) and a Rippability Study was done May 15, 1992 (Converse Project No. 91-33298-03).

OBSERVATIONS AND TEST RESULTS

The opinions and recommendations presented hereafter are based upon our tests and periodic observations of the grading procedures, and represent our engineering judgment as to the contractor's general compliance with the drawings and job specifications.

The grading operations were observed to be performed in the following general manner:

1. Vegetation, undocumented fill, rubble, trash, debris and any loose or disturbed soils should be removed from within the proposed dike, floodway and inlet structure areas.
2. The exposed native soils were scarified, moisture-conditioned as required, and recompacted to approximately 9 inches in depth.
3. Fill soils complying with the job requirements were placed in layers on the prepared surface, and each layer was compacted to the specified density before the next layer was added.

4. The minimum acceptable degree of compaction was 95 percent of the maximum density with a moisture content within 2% of optimum.

5. Maximum density and optimum moisture content were determined by the ASTM D1557-91 method.

6. All field density tests and their approximate locations are given in the enclosed Table I of the Table of Test Results. The approximate locations of the tests and the limits and depths of fill as observed during pad construction are shown on the project grading plans on file in our office.

7. The soil used in the compacted fill consisted of brown silty gravel with sand. A list of soil types encountered during testing and the maximum density-optimum moisture relation are given on Figure No. 1 through 4. Gradation results are given on Figures 5-7.

8. Core samples and compaction tests of the soil cement were taken during the construction in order to determine if the minimum compressive strength was achieved. The minimum acceptable degree of compaction for soil cement was 95 percent of the maximum density.

EROSION PROTECTION

The on-site granular soils are subject to erosion due to high water velocities. Therefore, erosion protection was required for inlet and bend areas, dike slopes, and along the floodway channel. Soil cement of 12 inch minimum thickness was used on the upstream slope of the dike. Erosion protection for the inlet area to the detention basin and for the transition from dike channel to floodway channel was also done by the use of soil cement.

Laboratory tests were performed on samples taken from the site as described in our letter dated January 7, 1992 (Converse Project No. 92-33421-01). The soil cement core samples were taken from the site as work progressed and brought to the lab in order to verify that minimum compressive strengths were being achieved. The results of these tests are included in the appendix of this report. Where applicable, the soil cement was placed in lifts and cored before the next lift was placed in order to determine if the minimum compressive strength was achieved.

CONCLUSIONS AND RECOMMENDATIONS

Based upon the results of the tests, observations of the construction procedures in the field, and our experience, it is our opinion that the compacted fill shown on the project grading plans has been placed in substantial compliance with the applicable portions of the job requirements and with the recommendations of Converse. Any fill added beyond the limits of above the grades shown should be placed under engineering observations and testing, and in accordance with the project requirements, if it is to be covered by the recommendations of this report.

The compacted fill discussed in this report was placed for support of a diversion dike. The foundation recommendations presented in the Geotechnical Investigation, dated January 8, 1992 (Converse Project No. 91-33298-01), are applicable to the diversion dike, floodway and inlet structure foundation materials.

The soil cement placed for erosion protection on the dike, floodway and inlet structure has also been placed in substantial compliance with applicable portions of the job requirements. The laboratory test results are included in appendices of this report.

CLOSURE

The conclusions and recommendations in this report are based on the results of our previous subsurface investigation and the observations of the construction procedures used during grading. If conditions are encountered during construction that appear to be different than those assumed in this report, this office shall be notified.

Our findings and conclusions have been obtained in accordance with accepted professional engineering practice in the field of Geotechnical Engineering. This warranty is in lieu of all other warranties, express or implied.

RE: RELEASE OF GIS DATA FOR RANGE WASH F.I.S. RESTUDY

Dear Mr. Graczyk:

Post, Buckley, Schuh & Jernigan, Inc. (PBS&J) has been awarded the contract for the "Range Wash F.I.S. Restudy" project by Clark County Regional Flood Control District (CCRFCD). To effectively accomplish this task, we need to acquire certain GIS data maintained in the Clark County Central Repository. As CCRFCD is amongst the inter-local agencies, it is our understanding that the data will be distributed at no cost. The project area is shown in the enclosed map, and we hereby request copies of the following Arc/Info coverages and associated relate tables over the geographic extent of the project:

Dear Ms. Valentine:

Enclosed please find an executed copy of the Agreement for Professional Services to prepare a Flood Insurance Restudy for the Range Wash in Clark County, dated July 13, 1995.

This letter will serve as the notice to proceed with the services described in the Agreement. Please coordinate your efforts with Kevin Eubanks of this office who will serve as the District's representative for the services.

Thank you for submitting the Agreement and Scope of Services in such a timely manner. We look forward to working with PBS & J. Please don't hesitate to contact me if you have any questions or require additional information.

Sincerely,

Gale Wm. Fraser, II, P.E.

I. INTRODUCTION

Post, Buckley, Schuh & Jernigan, Inc. (PBS&J), under contract with the Clark County Regional Flood Control District (CCRFCD), is preparing a Flood Insurance Restudy of the Range Wash, located within the City of North Las Vegas, and Clark County, Nevada. This hydrologic analysis is presented for review and approval of the 100-year peak flows presented herein.

II. PROJECT DESCRIPTION

Figure 1 shows the approximate limits of the study area. **Figure 2** shows a schematic of the Range Wash system. The lower reach of the Range Wash is commonly known as the Sloan Channel. The scope of work for this restudy includes the Western Tributary of the Range Wash and the Sloan Channel. The Eastern Tributary is not included because no significant development is present and no Special Flood Hazard Areas are identified in the area.

The purpose of this restudy is to update the Special Flood Hazard Areas due to two major flood control facilities which reduce the 100-year flow to the Range Wash and Sloan Channel. The two major flood control facilities are the West Range Wash Diversion Dike (completed in 1994) and the Confluence Detention Basin (currently under construction). There are two areas of Flood Zone "A" which are to be evaluated, and reduced or eliminated, as part of this study.

The West Range Wash Diversion Dike, located near the Grand Teton Drive alignment, is the northern boundary of the study area. The dike has reduced the 100-year flow to the Range Wash by diverting upstream flows from a 48 square mile area to the North Las Vegas Detention Basin on the Las Vegas Wash. The North Las Vegas Detention Basin is currently being study by FEMA Region IX. The construction of this facility is expected to impact the Zone "A" area upstream of Las Vegas Boulevard. **Figure 3**, a copy of the DFIRMs, Map Numbers 32003 C 1790 D, 32003 C 2180 D and 332003 C 2176D, for Clark County and Incorporated Areas, effective date August 16, 1995, shows the Flood Zones "A" in this area.

The Confluence Detention Basin, presently under construction, is located upstream of the Sloan Channel reach of the Range Wash system and is expected to reduce the 100-year peak flow to the Sloan Channel. Information on the Confluence Detention Basin is included in the hydrology for this restudy so that a Conditional Letter of Map Revision (CLOMR) may be obtained. **Figure 4**, a copy of the DFIRM, Map Number 32003 C 2200 D, for Clark County and Incorporated Areas, effective date August 16, 1995, shows the Flood Zones "A" associated with the Sloan Channel.

III. HYDROLOGY STUDY METHODOLOGY

This section presents the criteria and methodology used in preparing the hydrologic analysis for the study area. The purpose of the hydrologic analysis is to establish and obtain approval of the 100-year peak flow rates to be used in the hydraulic analysis for floodplain delineation.

A. Previous Hydrology Studies

Previous hydrology studies used as a basis for this model are listed below:

- *Hydrologic Analysis, Western and Eastern Tributaries of Range Wash*, Boyle Engineering, April 1990 (Boyle, 4-90);
- *Final Predesign Memorandum, Confluence Detention Basin and Sloan Channel Improvements*; Boyle Engineering, October 1992 (Boyle, 10-92);
- *Conceptual Master Drainage Study for Lewis Homes - Orchards*; Pentacore Engineering; January 1992 (Pentacore, 1-92).

Hydrology for the Confluence Detention Basin (Boyle, 10-92), is similar to the hydrology for the Western and Eastern Tributaries of Range Wash (Boyle, 4-90), but with modifications to include the Confluence Detention Basin and the future East Range Wash Detention Basin. Hydrology for the Orchards 432-acre community is more detailed than the Confluence Detention Basin hydrology in the area between Charleston Boulevard and Sahara Avenue, as flows at several concentration points and drainage facilities for that development are quantified. The hydrology for this restudy is a modified version of these three models. The modifications include:

- Modeling the Confluence Detention Basin that is currently under construction, but excluding the future East Range Wash Detention Basin.
- Delineating slightly different or additional subbasins, to account for different or additional concentration points;
- Considering new flood control facilities that affect drainage basin boundaries;
- Calculating slightly different basin areas, as basins are digitized from USGS Quadrangles, and areas are computed using Geographical Information Systems (GIS) rather than a planimeter;

- Updating the land use for existing conditions (using recent GIS parcel information and aerial photographs as guides), and calculating some different curve numbers, lag times and flow routes, to account for the new development in some of the basins;

- Using a different method for calculating lag times. The Boyle models used the method presented in the *SCS National Engineering Handbook, Section 4 - Hydrology* (SCS, 1972). This study used methods specified in the *CCRFCD Hydrologic Criteria and Drainage Design Manual* (described in detail in the **Appendix** of this report).

B. Drainage Basins

Figures 5A and **5B** show drainage basins and flow concentration points established for this study. **Figure 5A** is at a scale of 1" = 7500'; **Figure 5B** is at a scale of 1" = 3000' and shows the USGS topography used to delineate the drainage basins. The labeling system for the basins and nodes (flow concentration points) is similar to the systems used in the previous drainage studies. Basins that have been modified are either labeled with an "M" after them (example 44-M) or are given a new name.

Some of the drainage basins that were significantly changed include those in the western portion of the Range Wash drainage area between the West Range Wash Diversion Dike and Las Vegas Boulevard. Those drainage basins were subdivided to obtain flows at various washes tributary to the Flood Zones "A" along Walnut Road and Vandenberg Drive (shown on **Figure 3**).

Nellis Boulevard is the revised western boundary of the watershed between Las Vegas Boulevard and Charleston Boulevard because Nellis Boulevard intercepts flows from the west. A 30-inch to 96-inch storm drain system in Nellis Boulevard discharges into the Las Vegas Wash at Bonanza Road.

C. Hydrologic Model

The hydrologic model is the HEC-1 Flood Hydrograph Package developed by the U.S. Army Corps of Engineers Hydrologic Engineering Center. The SCS Dimensionless Unit Hydrograph Method prescribed in the CCRFCD *Hydrologic Criteria and Drainage Design Manual* (CCRFCD Manual) was used to develop hydrographs for each basin. The rainfall, storm centering, runoff loss rate and lag time data in the hydrologic analysis were prepared in accordance with the CCRFCD Manual. The CCRFCD criteria tables used in determining the drainage basin parameters are included in the **Appendix**.

Section 4 - Mapping Information

D. Rainfall

The peak flows to be used in determining floodplains for this Flood Insurance Restudy are those that may be expected during a 100-year rainfall event. In accordance with the CCRFCD Manual, the 100-year recurrence interval storm was based on a single event with a six-hour duration.

The majority of the drainage basins lie within the McCarran Airport Rainfall Area. The 100-year point rainfall values for drainage basins within the McCarran Airport Rainfall Area were obtained from Table 505 in the CCRFCD Manual. Within the McCarran Airport Rainfall Area, the 100-year, six-hour duration adjusted point rainfall is 2.77 inches. Some drainage basins are located partially or totally out of the McCarran Airport Rainfall Area. The point rainfall values for those drainage basins range between 2.77 and 3.00 inches, and were obtained from Figure 506 and Table 501. Figure 506 is an isohyetal map reproduced from the National Oceanic and Atmospheric Administration (NOAA) Atlas 2, "Precipitation - Frequency Atlas of the Western United States, Volume VII - Nevada," dated 1973. Table 501 in the CCRFCD Manual gives precipitation adjustment ratios for the Clark County area used to multiply rainfall data obtained from the NOAA Atlas 2. The adjustment ratios were determined by the U.S. Corps of Engineers, Los Angeles District in 1988. In the Appendix, **Figure A1** shows the 100-year isohyets, and point rainfall values for each basin are summarized on **Table A7** in the **Appendix**.

E. Storm Distribution and Storm Centering

The CCRFCD Manual uses storm distributions established by the Los Angeles District of the Corps of Engineers. For contributing drainage areas less than ten square miles, Storm Distribution 3 (SDN 3) is used. For contributing drainage areas greater than ten square miles, Storm Distribution 5 (SDN 5) is used.

Table 502 in the Clark County Regional Flood Control District Manual gives six-hour depth-area-reduction-factors (DARFs) to be used in centering storms over large drainage areas. Since the NOAA Atlas 2 precipitation depths represent the rainfall frequency at an isolated point, and a storm that extends over a large area typically has more intense rainfall occurring near the center of the storm, a DARF is applied to adjust the point rainfall values downward to represent an average depth of rainfall over the entire storm area. In the **Appendix**, **Table A1** indicates storm centering by summarizing key concentration points, with contributing basin areas and DARFs.

Fourteen different storm centerings for several nodes of interest are modeled. Nine storm centerings are considered for the Flood Zone A area (shown on **Figure 3**) that extends from Las Vegas Boulevard to north of Losee Road. Five storm centerings are considered for the Flood Zone A in the Sloan Channel area (shown on **Figure 4**) that extends from Owens Avenue to the confluence with the Las Vegas Wash near Vegas Valley Drive.

Table 1, in the Section IV, Hydrologic Results portion of this study, describes each node of interest, its contributing drainage area, SDN, DARF, and 100-year peak flow, and indicates which HEC-1 model contains that flow.

F. Runoff Loss Rates

The U.S. Department of Agriculture Soil Conservation Service (SCS) curve number (CN) methodology was used to model rainfall volume losses due to initial wetting, interception, infiltration, depression storage and evapotranspiration. Table 602 in the CCRFCD Manual was the basis for determining composite curve numbers for drainage basins based on soil type and land use. GIS procedures were used to calculate the composite curve numbers by integrating the soils, land use, and drainage basin information.

Soils information was obtained from the Soil Conservation Service (SCS) *Soil Survey of the Las Vegas Valley Area, Nevada*, (1982). Soils information beyond the limits of the published survey were taken from maps included in the *Western and Eastern Tributaries of Range Wash, Flood Control Facility Plan* (Boyle, 1991). Soils information in that study was provided by Clark County Soil Conservation Service personnel. Table 15 in the SCS soil survey, entitled "Soil and Water Features," classifies soils as type A, B, C or D. **Figure A2**, included in the **Appendix**, shows the soils in the area.

Land use, obtained from Geographic Information System (GIS) parcel information and recent aerial photographs, was divided into seven broad categories based on hydrologic characteristics. **Figure A3**, included in the **Appendix**, shows the land use in the area.

Tables A2 and **A3** summarize the curve numbers used for each soil type and land use. **Table A7** summarizes the weighted curve numbers derived for the drainage basins. The methodology for calculating the curve numbers is given in the **Appendix**.

G. Lag Time

Lag times were calculated in accordance with the CCRFCD Manual. For drainage basins with areas less than one square mile, a CCRFCD Standard Form 4 was completed and the time of concentration is calculated. For drainage basins with areas over one square mile, the United States Bureau of Reclamation (USBR) method is used to calculate lag time for use in the SCS Dimensionless Unit Hydrograph Method. Lag time parameters are included in **Tables A5, A6** and **A7**, and equations are included in the **Appendix**.

The average basin slopes were determined using elevations from the USGS 7.5 Minute Topographic Quadrangles. For the Orchards drainage basins, slopes were determined using information from the Orchards hydrology study (Pentacore, 1-92). In determining the watershed length and average slope for drainage basins that begin with steep, mountainous areas, the 15-85 convention used by the Army Corps of Engineers (COE) is used. With this method, the watershed length and slope do not include either the steep mountainous path at the beginning 15+/- percent of the total basin length, or the flattest path of the basin, assumed to start at about 85+/- percent of the total basin length. With this type of situation, the resulting slope taken from the middle portion of the watershed better represents the average basin parameters. Slope calculations for the drainage basins are presented in **Table A4** in the **Appendix**.

H. Hydrologic Routing

The CCRFCD Manual recommends Muskingum routing for channels that are not well-defined, and Kinematic Wave routing for channels that are well-defined. The Muskingum method provides for some of the effects of channel storage, so some runoff attenuation occurs during the routing. The Kinematic Wave method is used for efficient drainage systems, so the hydrograph is translated, but not attenuated. Equations used to determine the parameters used in the Muskingum routing are included in the **Appendix**. The Muskingum parameters are summarized on **Table A8**, and the Kinematic Wave parameters are summarized on **Table A9** in the **Appendix**.

IV. HYDROLOGIC RESULTS

Table 1 summarizes the hydrologic results for this Flood Insurance Restudy by describing each node of interest, its contributing drainage area, SDN and DARF, presenting the 100-year peak flow, and indicating which HEC-1 model contains that flow. Nodes G1, G2, G3, G4, G7, F3 and F4 are the nodes of interest in the Upper West Range Wash Flood Zone A area (shown on **Figure 3**) that extends from Las Vegas Boulevard to north of Losee Road. Nodes DB.IN, V1, V2, 50B-M, STEW, and CC are the nodes of interest in the Lower Range Wash (Sloan Chanel) Flood Zone A area (shown on **Figure 4**) that extends from Owens Avenue to the confluence with the Las Vegas Wash near Vegas Valley Drive.

Hydrologic results show that for the Sloan Channel, the more intense storms that control the peak flow are those centered only on the drainage basins downstream of the Confluence Detention Basin.

The Cibola development (also known as Magnolia Estates) on the southwest corner of Stewart Avenue and the Sloan Channel, is seeking a LOMR for the interim condition, before the detention basin is completed. The Case Number is 95-09-1021C. To accommodate there LOMR application, an HEC-1 model was prepared to determine the existing flow at this site, without the detention basin completed. The flow of 5,030 cfs is less than the previously estimated flow of 5,500 cfs.

Table 1: Hydrologic Results

Flow Node	Node Description	Drainage Area (sq.mi.)	DARF	SDN	HEC-1 Model	100-Yr Peak Flow

V. COMPARISON TO PREVIOUS STUDIES

As outlined in the Previous Hydrology Study section of this report, hydrology for this report has been changed from previous reports mainly to account for different or additional flow concentration points, new development and flood control facilities in the existing condition subbasins, and a different method for calculating lag times.

The flowrates determined in this Flood Insurance Restudy are, in general, close to flowrates determined for existing conditions in previous studies, until the Orchards basins are used and flow rates are increased. The difference is mainly due to use of higher rainfall for the Orchards area. **Table A10** in the **Appendix** compares the hydrologic parameters used in the Confluence Detention Basin or Orchards hydrology with the hydrologic parameters used in this Flood Insurance Restudy. Because many subbasins in this Flood Insurance Restudy were changed, a direct comparison of hydrologic parameters could not always be made. In those cases, basin areas and lag times could not be compared, but curve numbers and rainfall could be approximately compared.

HYDROLOGIC PARAMETER DETERMINATION

HYDROLOGIC PARAMETER DETERMINATION

A. Curve Numbers

For each soil type, **Table A2** calculates curve numbers (based on CCRFCD Table 602) for open land in its natural condition (Open Natural), and for open land in good condition (Open Good, grass cover greater than 75%). These curve numbers are then used in **Table A3** as land use components. For each soil type, **Table A3** uses three land use components, (Open Natural, Open Good, and Impervious) to calculate curve numbers for seven land use classifications. **Table A3** shows the land use component percentages used for each land use classification. For example, in determining a weighted curve number for a golf course, the area is estimated to be 5% Open Natural, 90% Open Good, and 5% Impervious. A weighted curve number for each drainage basin was calculated, based on the areal components of each drainage basin. Calculations were performed using the GIS capabilities of integrating the digitized drainage basin, soil type and land use information with data from **Table A3**. **Table A7** summarizes the weighted curve numbers derived for the drainage basins.

B. Lag Time

Lag times were calculated in accordance with the CCRFCD Manual. For drainage basins with less than one square mile, a CCRFCD Standard Form 4 was completed and the time of concentration was calculated. For drainage basins with over one square mile, the United States Bureau of Reclamation (USBR) method is used to calculate lag time for use in the Soil Conservation Service (SCS) Dimensionless Unit Hydrograph Method.

The average basin slopes were determined using elevations from the USGS 7.5 Minute Topographic Quadrangles. For the Orchards drainage basins, slopes were determined using information from the Orchards hydrology study (Pentacore, 1-92). Calculations are summarized in **Tables A5** and **A7**.

In determining the watershed length and average slope for drainage basins that begin with steep, mountainous areas, the 15-85 convention used by the Army Corps of Engineers (COE) is used. With this method, the watershed length and slope do not include either the steep mountainous area at the beginning 15+/- percent of the total basin length, or at the flattest part of the basin, assumed to start at about 85+/- percent of the total basin length. With this type of situation, the resulting slope taken from the middle portion of the watershed better represents the average basin parameters. Lag time parameters for these basins are presented in **Tables A6** and **A7**.

1. Upland Method for Small Drainage Basins

For drainage basins with less than one square mile, the time of concentration is calculated as follows:

$$T_c = T_i + T_t$$

Where:

T_c = Time of concentration (minutes)

T_i = Initial, inlet or overland flow time (minutes)

T_t = Travel time in the ditch, gutter, etc.. (minutes)

The Lag time for basins under one square mile is calculated as follows:

$$T_{lag} = 0.6T_c \text{ (hours)}$$

Initial flow time is calculated as follows:

$$T_i = 1.8(1.1 - K)L_o^{1/2}/S^{1/3}$$

Where:

T_i = Initial overland flow time (minutes)

K = $0.0132 * CN - 0.39$

CN = Curve Number

L_o = Length of overland flow (max. 500 ft)

S = Average basin slope (percent)

Travel time is calculated as follows:

$$T_t = L_t/(60\ V)$$

Where:

T_t = Travel time in the ditch, gutter, etc.. (minutes)

L_t = Travel Length (feet)

V = Average velocity of flow (ft/s)

The average velocity was determined using the following equation, which produces results equivalent to CCRFCD Figure 602 for overland flow. The equation is found in *Hydrologic Analysis and Design*, by Richard H. McCuen, 1989. A copy of the reference is included in the CCRFCD Criteria section of this **Appendix**.

$$V = kS^{1/2}$$

Where:

V = Average velocity of flow (ft/s)

S = Average basin slope (percent)

k = A parameter that represents land cover

k	Land Use / Flow Regime
0.70	Short grass pasture (overland flow)
0.90	Cultivated straight row (overland flow)
1.00	Nearly bare and untilled (overland flow)
1.00	Alluvial fans in Western mountain regions
1.50	Grassed waterway
2.00	Paved area (sheet flow)
2.00	Small upland gullies

The CCRFCD Manual states that the time of concentration for the first design point in an urbanized basin using the Upland Method should not exceed the time of concentration calculated using the following equation:

$T_c = L/180 + 10$

Where:

T_c = Time of concentration at the first design point in an urban watershed (minutes)

L = Watershed Length (feet)

The lag time used for each urban drainage basin (with an area less than one square mile) was the lesser of the values obtained using the equations presented above. Calculations for these basins are presented on **Tables A4** and **A5**.

2. United States Bureau of Reclamation Method for Large Drainage Basins

The lag time for basins over one square mile is calculated as follows:

$$T_{lag} = 20\ K_n [L\ (L_c/S^{1/2})]^{1/3}$$

Where:

T_{lag} = Lag time (hours)

L = Watershed Length, length of longest watercourse (miles)

L_c = Length along longest watercourse measured upstream to a point opposite the centroid of the basin (miles)
(Note: Assume Lc is half of L)

S = Average slope of the longest watercourse (feet per mile)

K_n = Manning's roughness for the basin channels

K_n	Water Course Description
0.015	In urbanized areas, streets, storm drains, improved channels
0.030	Well-defined, unimproved channels or washes, minimal vegetation)
0.050	Not well-defined, small rills and braided wash areas
0.050	Mountainous channels with large boulders and flow restrictions

For basins in which several runoff paths are scattered throughout the basin, and there is not one main tributary watercourse, a Manning's roughness of 0.06 is used, as velocities are anticipated to be slower due to runoff being distributed in several paths, instead of in one main watercourse.

USBR Lag calculations for basins over one square mile are presented on **Tables A6** and **A7**.

RUNOFF CURVE NUMBERS
(URBAN AREAS[1])

Cover description		Curve numbers for hydrologic soil group—			
Cover type and hydrologic condition	Average percent impervious area[2]	A	B	C	D
Fully developed urban areas (vegetation established)					
Open space (lawns, parks, golf courses, cemeteries, etc.)[3]:					
Poor condition (grass cover < 50%)		68	79	86	89
Fair condition (grass cover 50% to 75%)		49	69	79	84
Good condition (grass cover > 75%)		39	61	74	80
Impervious areas:					
Paved parking lots, roofs, driveways, etc. (excluding right-of-way)		98	98	98	98
Streets and roads:					
Paved; curbs and storm sewers (excluding right-of-way)		98	98	98	98
Paved; open ditches (including right-of-way)		83	89	92	93
Gravel (including right-of-way)		76	85	89	91
Dirt (including right-of-way)		72	82	87	89
Western desert urban areas:					
Natural desert landscaping (pervious areas only)[4]		63	77	85	88
Artificial desert landscaping (impervious weed barrier, desert shrub with 1- to 2-inch sand or gravel mulch and basin borders)		96	96	96	96
Urban districts:					
Commercial and business	85	89	92	94	95
Industrial	72	81	88	91	93
Residential districts by average lot size:					
1/8 acre or less (town houses)	65	77	85	90	92
1/4 acre	38	61	75	83	87
1/3 acre	30	57	72	81	86
1/2 acre	25	54	70	80	85
1 acre	20	51	68	79	84
2 acres	12	46	65	77	82
Developing urban areas					
Newly graded areas (pervious areas only, no vegetation)[5]		77	86	91	94

[1]Average runoff condition, and $I_a = 0.2S$.
[2]The average percent impervious area shown was used to develop the composite CN's. Other assumptions are as follows: impervious areas are directly connected to the drainage system, impervious areas have a CN of 98, and pervious areas are considered equivalent to open space in good hydrologic condition. CN's for other combinations of conditions may be computed using figure 603
[3]CN's shown are equivalent to those of pasture. Composite CN's may be computed for other combinations of open space cover type.
[4]Composite CN's for natural desert landscaping should be computed using figure 603 based on the impervious area percentage (CN = 98) and the pervious area CN. The pervious area CN's are assumed equivalent to desert shrub in poor hydrologic condition.
[5]Composite CN's to use for the design of temporary measures during grading and construction should be computed using figure 603 based on the degree of development (impervious area percentage) and the CN's for the newly graded pervious areas.

SCS TR-55, USDA, June 1986.

Velocities for Upland Method of Estimating Tc

however, given the relatively small drainage areas used in calibrating the models, the coefficients probably reflect significant portions of overland flow travel time.

The SCS Lag Formula. The Soil Conservation Service (SCS) provided an equation for estimating the watershed lag, which was defined as the time in hours from the center of mass of the excess rainfall to the peak discharge; they also indicate that the time of concentration equals 1.67 times the lag. Equation 3-39 is intended for use on watersheds where overland flow dominates and was developed for nonurban watersheds. The SCS recommends that the lag equation be used for homogeneous watersheds 2000 acres and less. Two graphs were provided by SCS in TR-55 (1975) for correcting the lag formula for use in urban areas. One factor is based on the percentage of imperviousness and curve number and the other on the percentage of the hydraulic length modified and the curve number. The method primarily reflects overland flow. The runoff curve number CN can be obtained from Table 7-6.

Velocity Methods. The velocity methods are based on the concept that the travel time (T_t) is a function of the length of flow (L) and the velocity (V):

$$T_t = \frac{L}{V} \tag{3-42}$$

in which T_t, L, and V have units of seconds, feet, and ft/sec, respectively. The travel time is computed for the principal flow path. Where the principal flow path consists of segments that have different slopes or land cover, the principal flow path should be divided into segments and Eq. 3-42 used for each flow segment. The time of concentration is then the sum of the travel times:

$$t_c = \sum_{i=1}^{k} T_{ti} = \sum_{i=1}^{k} \frac{L_i}{V_i} \tag{3-43}$$

in which k is the number of segments and the subscript i refers to the flow segment.

The velocity of Eq. 3-42 is a function of the type of flow (overland, sheet, rill and gully flow, channel flow, pipe flow), the roughness of the flow path, and the slope of the flow path. Some methods also include a rainfall index such as the 2-year, 24-hr rainfall depth. Flow velocities in pipes and open channels can be computed using Manning's equation:

$$V = \frac{1.49}{n} R_h^{2/3} S^{0.5} \tag{3-44}$$

in which V is the velocity (ft/sec), n is the roughness coefficient, R_h is the hydraulic radius (feet), and S is the slope (ft/ft). A number of methods have been developed for estimating the velocity. Overland flow or sheet flow can be estimated using a relationship between the velocity and the slope:

$$V = kS^{0.5} \tag{3-45}$$

in which V is the velocity (ft/sec) and S is the slope (percent). The value of k is a function of the land cover, with values for five land covers (forest, trash fallow, short grass pasture, cultivated, and nearly bare) given in Table 3-12. These are also shown in Fig. 3-13.

TABLE 3-12 Coefficients of velocity versus slope relationship for estimating travel times with the velocity method

k	Land Use/Flow Regime
0.25	Forest with heavy ground litter; hay meadow (overlow flow)
0.50	Trash fallow or minimum tillage cultivation; contour or strip cropped, woodland (overland flow)
0.70	Short grass pasture (overland flow)
0.90	*Cultivated straight row (overland flow)*
1.00	Nearly bare and untilled (overland flow); alluvial fans in western mountain regions
1.50	Grassed waterway
2.00	Paved area (sheet flow); small upland gullies

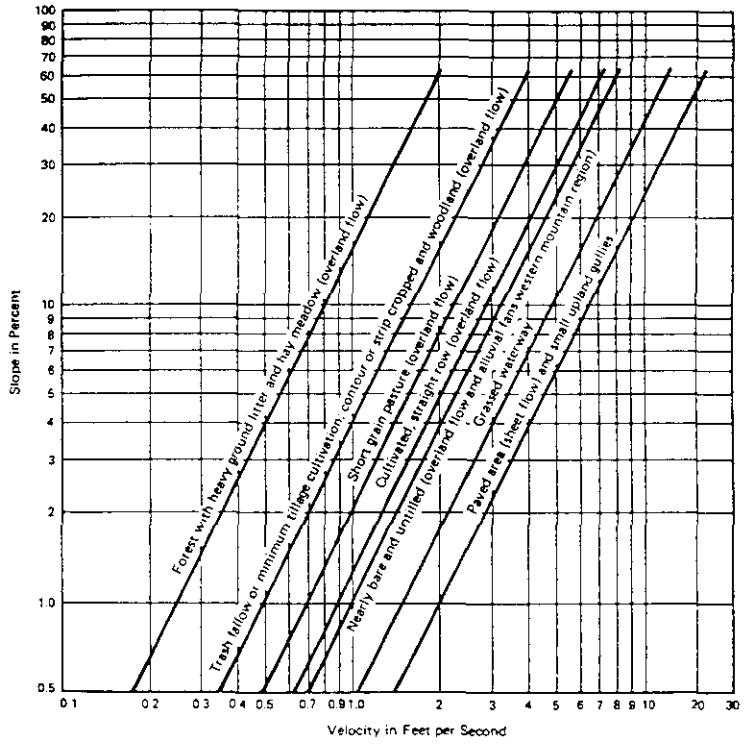

Fig. 3-13 Velocities for upland method of estimating T_0.

SELECTION CRITERIA: USBR Equation used for basins larger thna 1 sq. mile; Use also for basin approximately 1 sq. mile - basins greater than .75 sq. miles

FEMA multiple channel equation accounts for slope and roughness coefficient. Dawdy equation assumes critical flow. Use FEMA equation for basins less than .75 sq. miles. Subbasin flow is typically shallow with multiple collectors and subcritical.

LAG804.XLS

Equation

RANGE WASH FLOOD INSURANCE RESTUDY

DRAINAGE BASIN LAG TIME CALCULATIONS

UNITED STATES BUREAU OF RECLAMATION (USBR) METHOD

for TABLE A6

For use in the SCS Dimensionless Unit Hydrograph Method

Per CCRFCD Hydrologic Criteria and Drainage Design Manual, Section 606.3

For drainage basins with areas greater than one square mile.

$$\text{(USBR) } T_{lag} = 20*K_n(L*L_c/S^{0.5})^{0.33}$$

T_{lag} = Lag time (hours)

K_n = Manning's roughness factor for the basin channels
From CCRFCD Table 604

K_n = 0.015 for urbanized areas where water courses consist of streets, storm sewers, and improved channels.

K_n = 0.030 where water courses are well-defined, unimproved channels or washes, and the watershed has minimal vegetation.

K_n = 0.050 where water courses are not well-defined, and consist of many small rills and braided wash areas. Runoff from the area combines slowly into channels. Includes mountainous channels with large boulders and flow restrictions.

L = Length of longest watercourse (miles)

L_c = Length along longest watercourse measured upstream to a point opposite the centroid of the basin (miles)
(Note: Assume L_c is half of L)

S = Average slope of the longest watercourse (feet per mile)

SHALLOW UNCONFINED FLOW

FEMA MULTIPLE CHANNEL METHODOLOGY

$B = 36.1 * Q^{0.4}$

MANNING'S EQUATION FOR A WIDE CHANNEL

$y = [(Qn) / (1.49\ S^{1/2}\ B)]^{3/5}$

$V = Q/A = Q/By$

$\mathbf{V = (Q^{0.24} * S^{0.3})/(3.3*n)^{0.6}}$

B = Multiple Channel Width (feet)

V = Velocity (ft/s)

A = Flow Area (sq. ft.)

Q = Flow (cfs)

y = Depth (feet)

n = Manning's roughness coefficient

S = Slope (ft/ft)

EQUATIONS USED IN DETERMINING MUSKINGUM ROUTING PARAMETERS

Dawdy Equations for a Single Channel Alluvial Fan Analysis

$$V = 1.506 * Q^{1/5}$$

Where:

Q = Flow (cfs)
V = Velocity (ft/s)

Muskingum Storage Time Constant Equation

$$K = L/(3600V)$$

Where:
K = Muskingum Storage Time Constant (hours)
L = Channel Reach Length (feet)
V = Velocity (ft/s)

Muskingum Weighting Factor (X)
(From Section 608.1 in the CCRFCD Hydrologic Criteria and Drainage Design Manual)

The Weighting Factor accounts for the peak flow reduction caused by channel routing. It generally varies from 0 to 0.5, with 0 representing a reservoir type peak reduction, and 0.5 representing no peak reduction. In the Clark County area, values could range from 0.15 for channel reaches with some storage in overbanks but few obstructions such as would be found on alluvial fans, to 0.10 for inadequate channels in developed basins where overbank flows would encounter severe obstruction and consequently be significantly attenuated. The following table summarizes the attenuation types.

Attenuation Type	Muskingum Weighting Factor
Reservoir	0.00
None	0.50
Alluvial	0.15
Obstructed	0.10

EQUATIONS USED IN DETERMINING MUSKINGUM ROUTING PARAMETERS

Integer Number of Steps (NSTEPS)

The integer number of steps represents subreaches. Each subreach is such that the total travel time through the reach is approximately equal to K, the Muskingum Storage Time Constant. To ensure the method's computational stability and the accuracy of the computed hydrograph, the routing reach should be chosen so that the number of steps falls between the boundary values given by the following equations.

Upper Boundary for Number of Steps	Lower Boundary for Number of Steps	Average Value for Integer Number of Steps **NSTEPS** =
NSTEPS-U = (2 K (1-X)) / T	NSTEPS-L = (2 K X) / T	(NSTEPS-U + NSTEPS-L) / 2

Where:

NSTEPS = Average Value for Integer Number of Steps
NSTEPS-U = Upper Boundary for Steps
NSTEPS-L = Lower Boundary for Steps
K = Muskingum Storage Time Constant
X = Muskingum Weighting Factor
T = Time Increment (hours)

For this worksheet, the average value for number of steps is the value entered into the HEC-1 routing routine.
If HEC-1 routing errors occur, then the value is changed to a different interger that falls within the upper and lower boundaries.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HYDRAULIC ANALYSIS AND FLOODPLAIN DELINEATION SUMMARY

General

Post, Buckley, Schuh & Jernigan, Inc. (PBS&J), under contract with the Clark County Regional Flood Control District (CCRFCD), is preparing a Flood Insurance Restudy of the Range Wash, located within the City of North Las Vegas, and Clark County, Nevada. This report summarizes the hydraulic calculations for delineating the 100-year floodplain by approximate methods.

The purpose of this restudy is to update the Special Flood Hazard Areas due to two major flood control facilities which reduce the 100-year flow to the Range Wash and Sloan Channel. The two major flood control facilities are the West Range Wash Diversion Dike (completed in 1994) and the Confluence Detention Basin (currently under construction).

There are two areas of Flood Zone "A" which were evaluated, and reduced or eliminated, as part of this study. The first area is associated with the West Tributary of the Range Wash. The current flood hazard zones and the proposed revised flood hazard zones are shown in **Figure 1**. The second area is along the Sloan Channel. **Figure 2** shows current and proposed flood hazard zones for this area. **(Note: See Section 4 Mapping Information for Figures 1-3.)**

The West Range Wash Diversion Dike, located near the Grand Teton Drive alignment, is the northern boundary of the study area. The dike has reduced the 100-year flow to the Range Wash by diverting upstream flows from a 48 square mile area to the North Las Vegas Detention Basin. Documentation for this facility is included in the Reference Materials Section of the Technical Support Data Notebook (TSDN).

The Confluence Detention Basin, presently under construction, is located upstream of the Sloan Channel reach of the Range Wash system and will reduce the 100-year peak flow to the Sloan Channel. Documentation for this facility is also included in the Reference Materials Section of the TSDN.

Channel improvements have also been constructed on the Sloan Channel between Owens and Stewart Avenues. Channel improvements are under construction on the West Tributary Channel between Lamb Boulevard and Alexander Avenue as part of the Collins Business Park. Documentation for these channel improvement projects is included in the TSDN.

Hydraulic Analyses were performed for the purpose of delineating the approximate 100-year floodplain boundaries. Base flood elevations are not determined for approximate methods. Analyses of the hydraulic characteristics of channels and flow paths were performed using normal depth calculations.

Normal depths were calculated using FlowMaster for Windows Version 5.11 distributed by Haestad Methods. Depths at culverts were determined using HY-8 Version 3.2, a non proprietary software package developed by the Federal Highway Administration and Pennsylvania State University for hydraulic designs of highway culverts.

The revised flood hazard areas may be divided into three areas: The Walnut Branch of the West Tributary, The Vandenberg Branch of the West Tributary, and the Sloan Channel Area.

The Walnut Road Branch

The current Flood Insurance Rate Maps (FIRM) indicate an A Zone along Walnut Road. The A Zone continues from Walnut Road following Maple Hill Road, Alexander Road, Lamb Road, and Faberge Avenue until it meets the main wash.

To evaluate the flows along the Walnut Road Branch, Subbasin 307E was subdivided into smaller basins. The two foot contour interval maps available from North Las Vegas, with flight date of March 3, 1995, were used to subdivide the basin. Flows were estimated based on the cfs/acre of the total basin. The more detailed subbasin map, with flow from each subbasin, is shown in **Figure 3**.

The culvert on Interstate 15 (I-15) upstream of Walnut Road creates a ponding area between I-15 and the Union Pacific Railroad (UPRR). This ponding area will continue to be an A Zone. Approximately 320 cfs reaches the I-15 culvert. The culvert detains flows in an impoundment area and would reduce the downstream peak flow. The City of North Las Vegas did not want to have a downstream flood hazard area removed, if it was dependent on the storage of the impoundment area. The ponding area will not be maintained and is expected to be filled by development in the near future. Therefore, no retention effect was considered.

The area in Walnut Road between Mitchell Street and the railroad crossing near Craig Road is continued to be mapped as an A Zone, with depth of slightly more than one foot and a width of approximately 190 feet (See Cross-Section A on the Work Maps and in the calculations). Approximately 300 cfs is estimated to flow in the street section and 20 cfs in the stormdrain system.

The railroad crossing near Craig Road produces a hump in the road, and removal of the normal crown. This causes a barrier to flow in the street. The majority of flow is diverted along the north side of the railroad tracks. Calculations for the flow split are included in this summary (See Cross-Section B). The tributary area between I-15 and the railroad tracks adds approximately 60 cfs to the flow, for a total flow of 380 cfs. At the railroad crossing, 235 cfs

flows along the railroad tracks, 125 cfs continues in the Walnut Road street section, and 20 cfs in the stormdrain.

The flows continuing in Walnut Road are less than a foot deep and contained within the street section, therefore, the A Zone does not continue in Walnut Road downstream of the railroad tracks (See Cross-Section C).

A flow of 15 cfs is assumed to flow to the intersection of Walnut Road and Craig Road from the west. A negligible amount of flow would go east in Craig Road. A flow of 140 cfs is assumed to cross Craig Road and continue in Walnut Road (See Cross-Section D).

There is a channel, just to the South of Craig Road, which conveys flow east to the main wash. The stormdrain empties into this channel. The curb in Walnut Road ends at the beginning of the channel causing flow on the east side of the street to spill into the channel. A flow of 70 cfs remains in the west side of the street, 45 cfs spills to the channel, 25 cfs continues in the east side of the street. Calculations for the flow split at this location are included in the summary calculations (See Cross-Section E). The flows in the street are less than one foot deep and not mapped as an A Zone.

Approximately 35 cfs flows to the intersection of Walnut Road and Maple Hill Road from the west, making a total street flow of 120 cfs. This flow follows Walnut Road. It is less than one foot deep and confined to the street section (See Cross-Section F). It is not mapped as an A Zone.

The flow increases to approximately 200 cfs at Alexander Road. There is a sump in Alexander Road west of Lamb Boulevard. A stormdrain system drains the sump, with a 48-inch pipe conveying flows east to the main wash. The pipe capacity is estimated to be 90 cfs. The sump area is assumed to spill equally to Lamb Boulevard and Steinbeck Street. A flow of 55 cfs is assumed in Steinbeck Street (See Cross-Section G) and in the west side of Lamb Boulevard. The depth of water in the sump location will be greater than one foot deep, but it will be a small area confined to the street section, approximately 100 feet wide, therefore it will not be shown as an A Zone. The flows in Steinbeck Street and in Lamb Boulevard are less than one foot deep.

The flows form Steinbeck Street, Lamb Boulevard and other tributary areas collect into Faberge Avenue. The estimated flow in Faberge Avenue is 175 cfs. This flow is contained in the street and is less than one foot deep (See Cross-Section H). There is an 18-foot wide channel at the end of Faberge Avenue which conveys the flow to the main wash (See Cross-Section I).

The flow which followed the railroad tracks, near Craig Road, is confined by a wall on the south side of the tracks, until it reaches Andrews Street. The tracks end at Andrews Street. The flow follows Andrews Street to Craig Road. The flow is too large to be contained within the street section. It flows to the main wash at the sag in Craig Road, at the downstream end of the Vandenberg Channel.

The Vandenberg Branch

The Vandenberg Branch has two branches upstream of the UPRR. The current FIRM shows an A Zone following the western branch approximately 5,000 feet upstream of the UPRR. The dike has reduced flows to this area and the hydrologic analysis indicates a flow for this branch of 530 cfs. Flows are contained within the well defined wash with a width of approximately 50 feet, and therefore, it is not mapped as an A Zone (See Cross-Sections J, K, and L) .

The Eastern Branch has an estimated flow of 1,060 cfs which collects at a bridge crossing of the UPRR. Upstream of the railroad, the washes are not significant to be mapped as A Zones.

Both branches collect and pond along the railroad and are shown as A Zones on the Work Maps.

The branches come together upstream of Vandenberg Drive. Vandenberg Drive has a trapezoidal channel located in the center median. The channel has an 8 foot wide base width. There is 50 foot wide paved street section on each side of the channel. The pavement slopes away from the channel on a 2% grade. There are several box culvert crossings in the channel. The channel begins at Lone Mountain Road where there are 2 10' x 3' box culvert cells. Approximately 500 cfs passes through the culvert and 970 cfs overtops and flows along the east side of Vandenberg Drive. Another culvert has 2 - 9'x 3' cells and restricts the flow in the channel to approximately 400 cfs. Culvert calculations, and normal depth calculations for cross-sections in the overbank area, are included in this summary and shown on the Work Maps (See Cross-Sections O - R).

Flows along Vandenberg Drive cross Craig Road and enter the natural wash. Flows are fairly confined downstream of Craig Road. There is not an existing A Zone downstream of Las Vegas Boulevard where the channel is improved and concrete lined. Channel cross-sections and culvert calculations along the reach between Craig Road and Las Vegas Boulevard are included in this summary and indicated on the Work Maps (See Cross-Sections S - W). A portion of the channel is presently under construction between Lamb Boulevard and Alexander Road. HEC-2 Water Surface Profile calculations for this reach are included in the Reference Materials Section of the TSDN. The reach of improved channel between Lamb Boulevard and Alexander Road is not shown as an A Zone, since flows are confined within the channel.

Sloan Channel Area

The detention basin will reduce flows so that they will be contained within the Sloan Channel. The A Zones along the Sloan Channel may be eliminated with one exception. There is and A Zone along Washington Avenue, east of Sloan Channel that is not impacted by new improvements.

The Channel along Washington Avenue intercepts flows which formerly reached Bonanza Road. The A Zone in Bonanza Road and following a southwest path to the Sloan Channel may be eliminated. There is a 72 -inch Stormdrain in Bonanza and full street improvements which have more capacity than the 100-year flow. The street and pipe capacity is 840 cfs, the 100-year flow is 320 cfs.

The drainage study for the Cibola (Also known as Magnolia Estates) private development on Stewart Avenue west of Sloan Channel is included in the TSDN. The study was used to estimate the flow splits and flows in the streets in that vicinity. The flows in that study correspond to the flows developed for the FIS Restudy. Calculations indicate flows in Battle Mountain Drive are less than 1 foot deep. Flows in Stewart Avenue west of Battle Mountain concentrate on the south side of the street with a depth of approximately 1.8 feet deep in the south side gutter. The improvements along Stewart include raising the grade of the proposed site to confine this flow to the street and then direct it into the Sloan Channel. Although there is a small segment of Stewart Avenue, between Battle Mountain Drive and Sloan Channel, where the depth will be greater than one foot deep, it is not mapped as an A Zone because it will be confined to the street section, only 80 feet wide with an average depth less than one foot of 0.87 feet..

There is a small isolated A Zone located along Charleston Boulevard west of the Sloan Channel. This A Zone may be eliminated due to full street improvements and Stormdrain in Charleston Boulevard.

Normal depth calculations for typical sections of Sloan Channel are included in this summary. HEC-2 Water Surface Profile calculations are included in the Predesign Report for the Channel included in the TSDN.

Project Description	
Project File	c:\haestad\fmw\range4.fm2
Worksheet	WEST VANDENBERG 2
Flow Element	Irregular Channel
Method	Manning's Formula
Solve For	Water Elevation

Input Data				
Channel Slope	0.008000 ft/ft			
Elevation range: 46.00 ft to 58.00 ft.				
Station (ft)	Elevation (ft)	Start Station	End Station	Roughness
0.00	58.00	0.00	210.00	0.030
40.00	56.00			
60.00	50.00			
100.00	48.00			
140.00	46.00			
150.00	46.00			
160.00	48.00			
210.00	54.00			
Discharge	530.00 cfs			

Results		
Wtd. Mannings Coefficient	0.030	
Water Surface Elevation	48.42	ft
Flow Area	97.76	ft²
Wetted Perimeter	72.21	ft
Top Width	71.92	ft
Height	2.42	ft
Critical Depth	48.21	ft
Critical Slope	0.012202	ft/ft
Velocity	5.42	ft/s
Velocity Head	0.46	ft
Specific Energy	48.88	ft
Froude Number	0.82	
Flow is subcritical.

VANDENBERG SECTION 3
Worksheet for Irregular Channel

Q

Project Description	
Project File	c:\haestad\fmw\range1.fm2
Worksheet	VANDENBERG SECTION 3
Flow Element	Irregular Channel
Method	Manning's Formula
Solve For	Water Elevation

Input Data		
Channel Slope	0.008000	ft/ft
Elevation range: 1.00 ft to 4.00 ft.		

Station (ft)	Elevation (ft)	Start Station	End Station	Roughness
0.00	4.00	0.00	60.00	0.018
60.00	2.00	60.00	230.00	0.030
75.00	1.00			
90.00	2.00			
230.00	4.00			

Discharge	1,020.00	cfs

Results		
Wtd. Mannings Coefficient	0.027	
Water Surface Elevation	3.65	ft
Flow Area	200.86	ft²
Wetted Perimeter	195.23	ft
Top Width	195.12	ft
Height	2.65	ft
Critical Depth	3.55	ft
Critical Slope	0.010502	ft/ft
Velocity	5.08	ft/s
Velocity Head	0.40	ft
Specific Energy	4.05	ft
Froude Number	0.88	
Flow is subcritical.

1.0 INTRODUCTION

1.1 Purpose of Study

This report presents the findings of the Range Wash Flood Insurance Study (FIS) Restudy. The purpose of this study was to update the Special Flood Hazard Areas, due to two major flood control facilities and miscellaneous development and improvements for the Range Wash in the City of North Las Vegas and Unincorporated Areas of Clark County, Nevada (**Figure 1**). The results of this flood risk study will be used to update the Flood Insurance Rate Maps (FIRM) for Clark County, Nevada and Incorporated Areas. The FIRMs are distributed by the Federal Emergency Management Agency (FEMA) to aid in the administration of the National Flood Insurance Program (NFIP). This program was established with the passage of the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973 to enable property owners to purchase insurance protection against losses from flooding.

1.2 Authority and Acknowledgments

Post, Buckley, Schuh & Jernigan (PBS&J) was authorized by the Clark County Regional Flood Control District (CCRFCD) to perform a study using approximate methods of the Range Wash on July 13, 1995.

1.3 Coordination

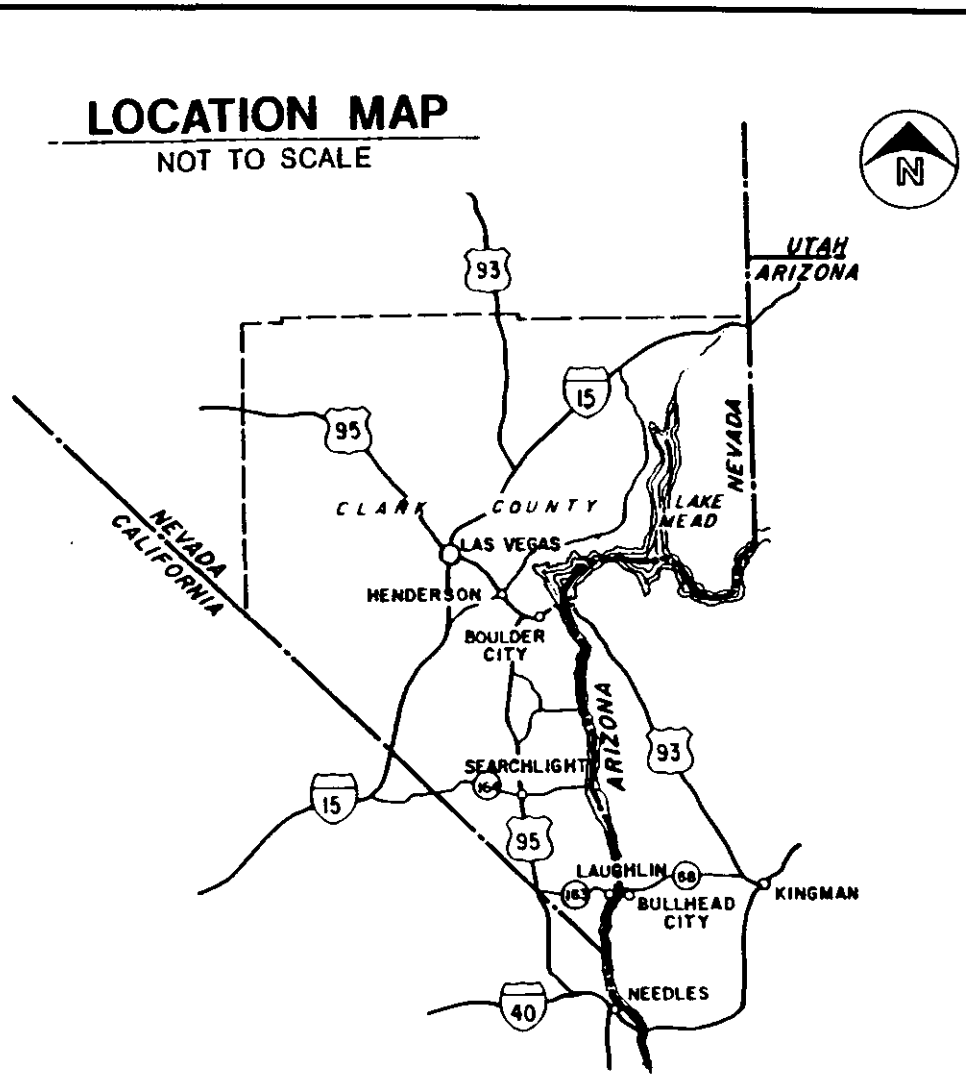
The area of study was identified during the project kick-off meeting on July 27, 1995 in which representatives of the CCRFCD, City of North Las Vegas (CNLV), Clark County Public Works Department (CCPW) and PBS&J attended.

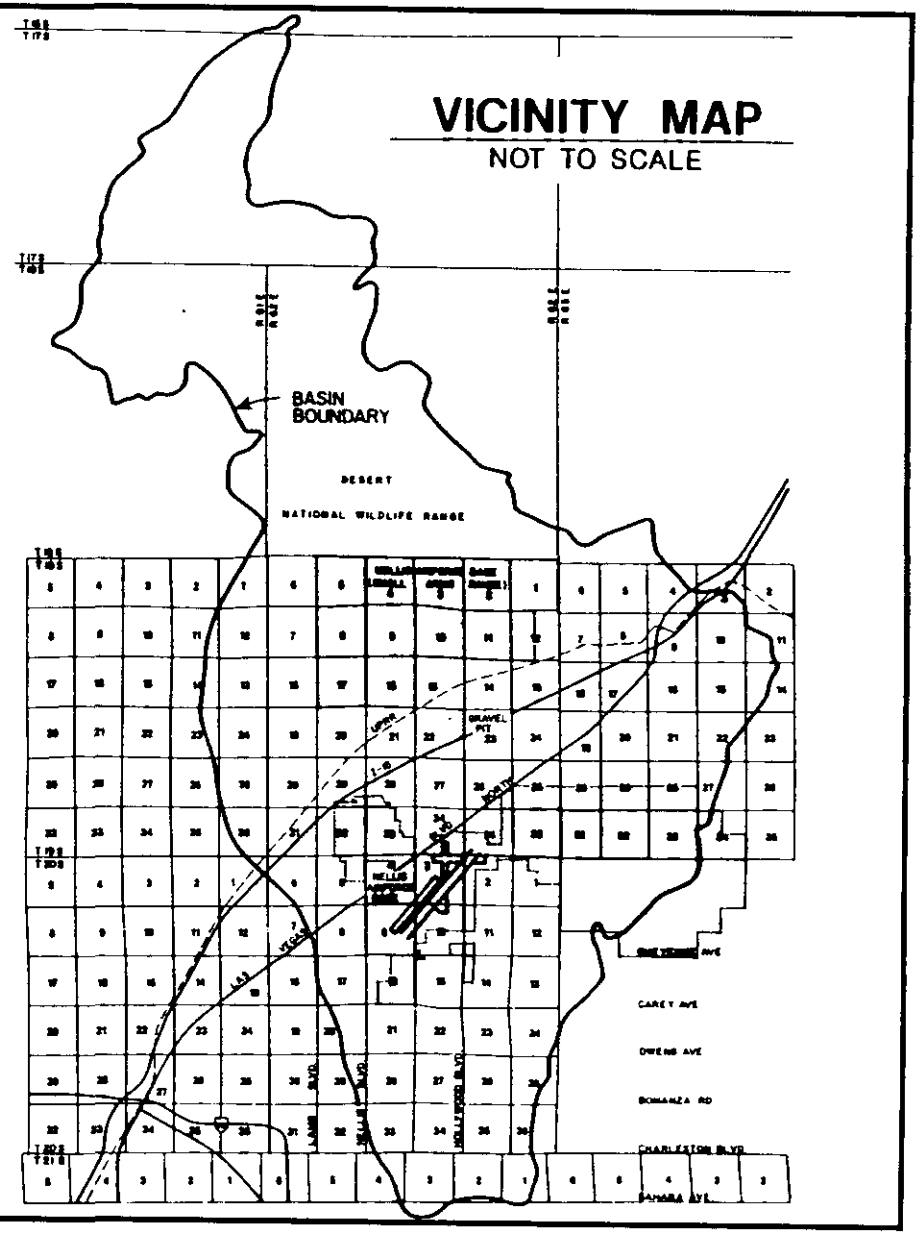
The results of the hydrologic analysis were coordinated with the CCRFCD, CNLV, and Clark County. Throughout the project, coordination meetings were held to discuss progress, hydrologic results and the floodplain delineation.

2.0 AREA STUDIED

2.1 Scope of Study

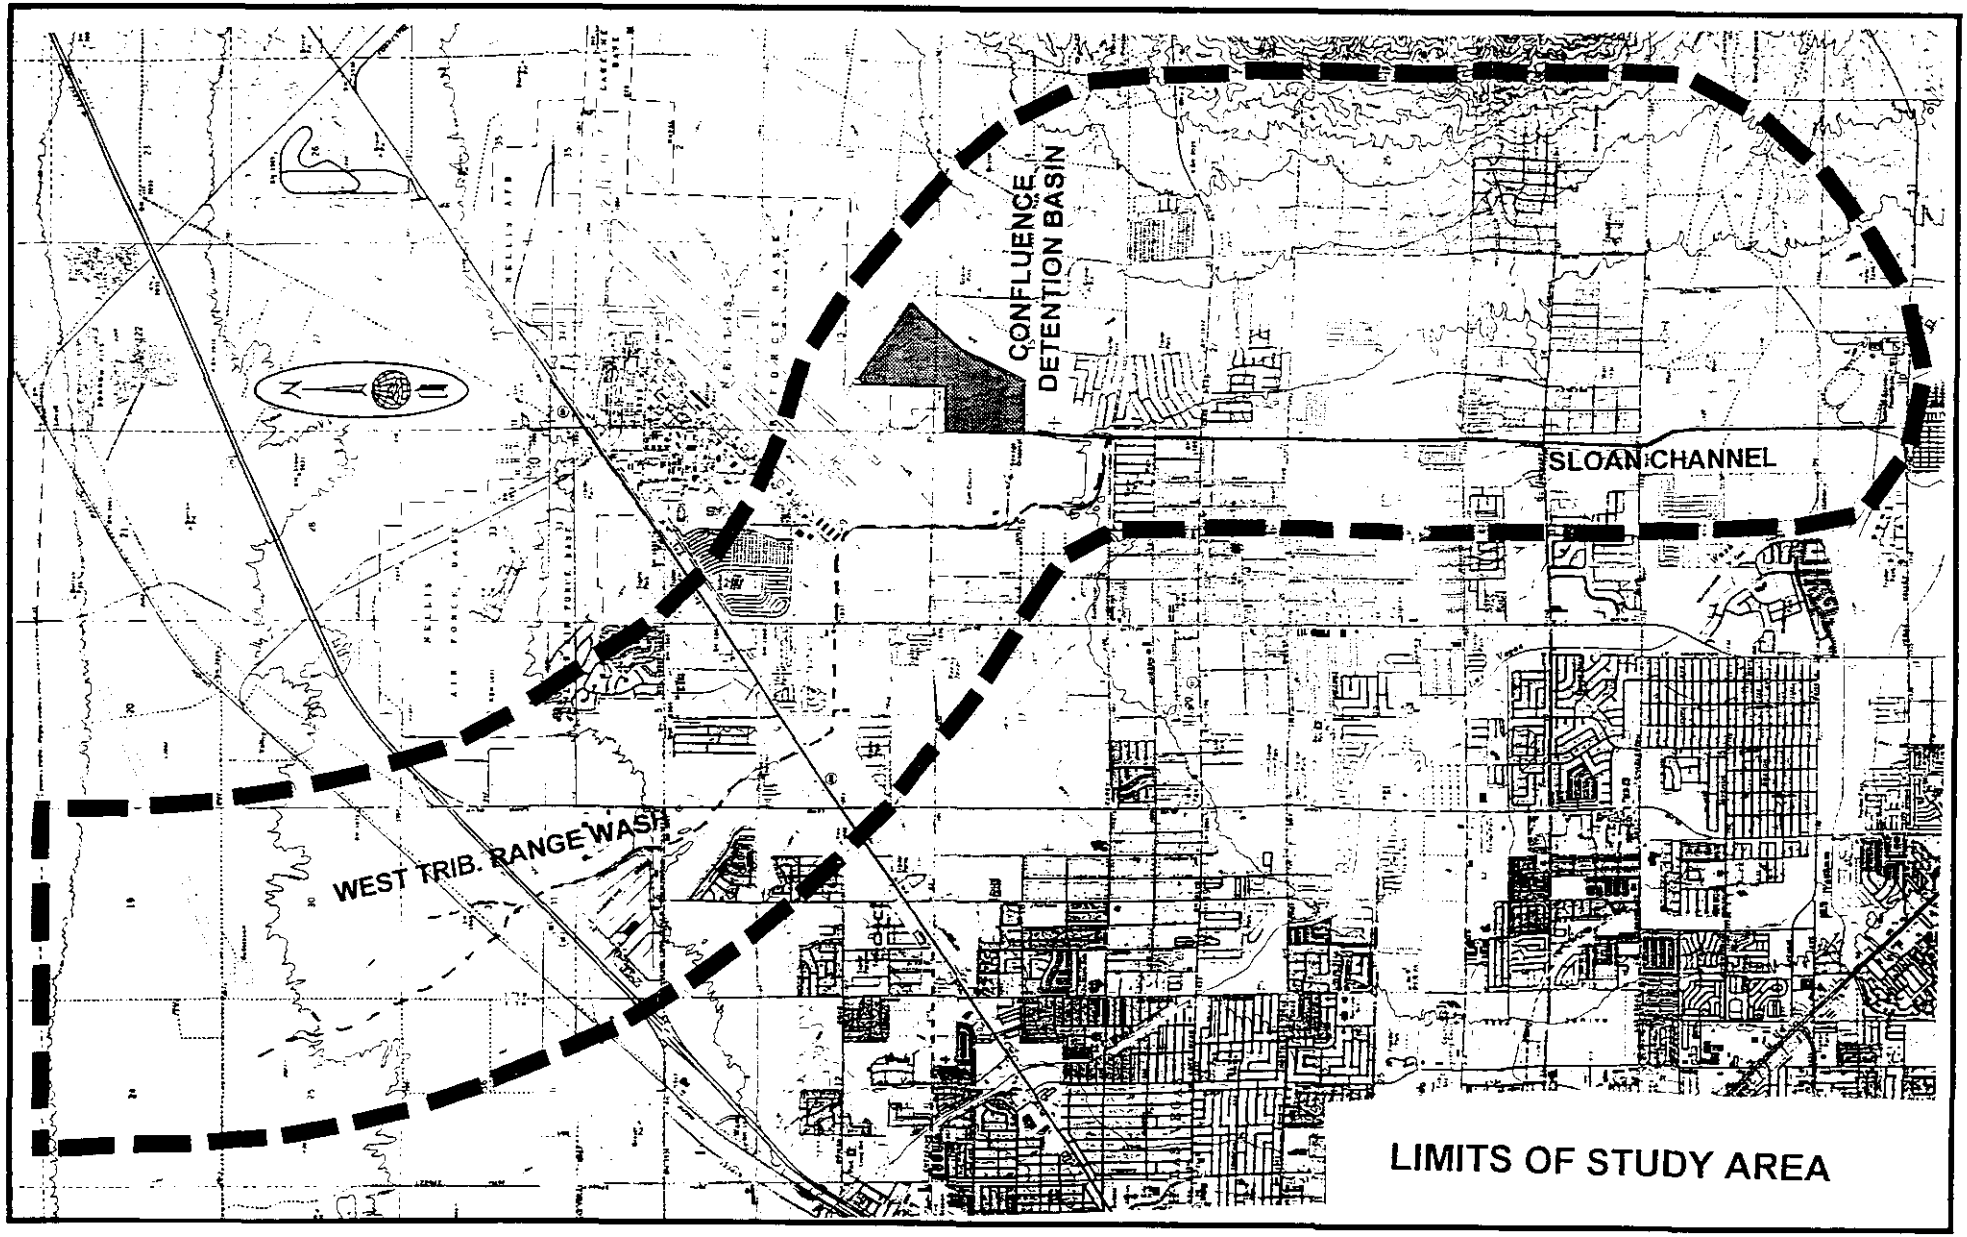
This study presents the findings of hydrologic and hydraulic analysis for the Range Wash located in City of North Las Vegas, and areas of Unicorporated Clark County, Nevada. The limits of Study Area are shown in **Figure 2**.





PBS&J POST, BUCKLEY, SCHUH & JERNIGAN, INC.

FIGURE 1



PBS&J POST, BUCKLEY, SCHUH & JERNIGAN, INC.

FIGURE 2

The Range Wash system is shown schematically in **Figure 3**.

The areas of special flood hazard areas of the previous FIS are divided into two areas, an upper reach on the West Tributary, and a lower reach on the Sloan Channel. See **Figures 4 and 5.** The results of the flood hazard delineation analysis are shown on **Figures 6 and 7.**

The scope included performing field reconnaissance, data collection and review, hydrologic analysis, hydraulic analysis and special flood hazard area delineation by approximate methods.

2.2 Community Description

The Range Wash drainage basin is located in the northeast portion of the Las Vegas Valley. The basin lies entirely within Clark County, Nevada and includes portions of City of North Las Vegas, Nellis Air Force Base, and portions of Unincorporated Clark County.

The Range Wash is a major tributary to the Las Vegas Wash. The basin is bound on the north by the Las Vegas and Sheep Range Mountains and on the East by the Frenchman Mountains.

The total watershed is approximately 150 square miles. Approximately 48 square miles of the West Tributary area is diverted by the West Range Wash Dike to the North Las Vegas Detention Basin and Las Vegas Wash System. There is approximately 24 square miles of the West Tributary downstream of the dike to the Confluence Detention Basin. There is approximately 58 square miles in the East Tributary to the Detention Basin. There are approximately 17 square miles below the detention basin to the confluence with the Las Vegas Wash (Reference 2).

The basin can be characterized by three distinct land types: Mountainous, alluvial fan, and urban developed. The mountainous regions of the watershed are steep and rocks with limited vegetation. The alluvial fan areas are characterized by alluvial deposits and numerous channels of limited capacity. The vegetation consists of desert shrubs and grasses. The Range Wash Dike diverts flows from the northern mountain region and upper portion of the fan of the West Tributary. A large portion of the fan below the dike remains presently undeveloped (Reference 2).

The majority of existing development is a mixture of residential and light commercial. The area in the vicinity of I-15 and UPRR is zoned industrial. Nellis Air Force Base development includes base housing, parks and golf courses, base office buildings, airfields and related services (References 2 & 25).

FIGURE 7

The East Tributary of the Range Wash is in undeveloped areas and is in a natural condition. The West Tributary is lined south of Las Vegas Boulevard to the Confluence with the Sloan Channel (References 21 & 22). There are improvements of limited capacity upstream of Las Vegas Boulevard. The Confluence Detention Basin is presently under construction (Reference 8). The Sloan Channel south of the detention basin is concrete lined to Bonanza Road and designed to Stewart Avenue (Reference 18). The channel is graded to its confluence with the Las Vegas Wash.

The climate in the Las Vegas area is arid with hot summers and mild winters. It is characterized by episodic rainfall and wide extremes in daily temperatures. Average daily minimum/maximum winter temperatures range from approximately 33/56 °F in the valley areas to about 17/35 °F in the mountains. This summer temperatures range from approximately 76/105 °F in the valley areas to 55/80 °F in the mountains (Reference 11).

The average annual precipitation in the Las Vegas Valley is approximately 4.2". During the winter period (October through April, inclusive), the primary source of moisture to this area is the Pacific Ocean. Precipitation results from frontal systems; and the events are low-intensity and long-duration. During the summer period (May through September, inclusive), the primary moisture sources are the Pacific Ocean, the Gulf of Mexico, and upwind land surfaces as well as reservoirs (Reference 11).

The soils are primarily classified as hydrologic soil group Type B on alluvial fan areas and D in mountainous areas (References 2 & 31).

2.3 Principle Flood Problems

The typical flood-producing storm causing flooding problems are associated with summer thunderstorms of short duration and high intensity which result in significant runoff rates. These storms result from tropical depressions from the south. Summer or winter general storms of longer duration and lower intensity have not contributed to significant discharges in the past.

Major flooding and damages along the Range wash occurred during a summer thunderstorm of July 28, 1984. In that storm 2.5 to 3.0 inches of rain fell over a large area including the Range Wash watershed (Reference 11). An upper reach of the West Tributary known as the Vandenberg Channel had inadequate capacity and road crossing were blocked by debris. An unlined portion of the Sloan Channel was breached due to inadequate capacity and embankment failure. Street flooding with damage to vehicles and residences occured at Mobile Home Park at Carey Avenue and Sloan Lane and along Linn Lane and Christy Lane.

2.4 Flood Protection Measures

Flows to the Vandenberg Channel have been reduced by the Range Wash Dike. Flow to Sloan Channel is reduced by the dike and the Confluence Detention Basin. More of the Sloan Channel has recently been concrete lined from Owens Avenue to Bonanza Road. Storm drain facilities have been constructed with street improvements in Bonanza Road, Nellis Boulevard and Charleston Boulevard.

The Range Wash Dike is designed for a 100-year flow of approximately 7,000 cfs including allowances for sediment and impact. The dike is 15 feet high with a 120 feet wide channel on the upstream side (Reference 6).

The Confluence Detention Basin has a storage volume of approximately 1,025 acre feet. It has a two level outlet that works in conjunction with a diversion structure on the West Tributary. The inflow under fully developed conditions is approximately 4,800 cfs. The outflow is limited to approximately 360 cfs until the basin is within 3 feet of the emergency spillway crest, at this location a secondary outlet begins operation increasing the outflow rate to approximately 1,800 cfs. The higher rate occurs after downstream hydrograph peaks have subsided (References 4,5 & 8).

3.0 ENGINEERING METHODS

3.1 Hydrologic Analyses

A hydrologic analysis was performed to determine 100-year discharges to estimate the limits of flooding. The hydrologic analysis was performed by using a rainfall runoff simulation model. The model used was the Corps of Engineers HEC-1 September 1990 version. The generated flows were consistent with previous studies and established regulatory discharges. The modeling procedures, calculations and results are included in the hydrologic report. The flows at key locations are summarized in Table 1.

3.2 Hydraulic Analyses

Hydraulic Analyses were performed for the purpose of delineating the approximate 100-year floodplain boundaries. Base flood elevations are not determined for approximate methods. Analyses of the hydraulic characteristics of channels and flow paths were performed using normal depth calculations.

Table 1: Summary of Discharges

Flooding Source & Location	Drainage Area (sq. mi.)	100-Yr Peak Discharges
West Tributary Range Wash		
Mitchell St. & Walnut Rd.	0.83	320
12'x 8' RCB at the UPRR U/S of Vandenberg	2.52	530
2 - 21'x 12' bridge cells at UPRR U/S of Vandenberg	5.53	1060
3- 15'x10' RCBs at I-15 U/S of Vandenberg	8.05	1470
7 - 10'x7' RCBs at LV Blvd.	11.08	1550
Range Wash		
Confluence Detention Basin	81.68	4180
Sloan Channel		
Sloan Channel at Bonanza Road	7.55	2570
Sloan Channel at Stewart Avenue	10.78	2620
Sloan Channel at Las Vegas Wash	17.11	4000

Normal depths were calculated using FlowMaster for Windows Version 5.11 distributed by Haestad Methods. Depths at culverts were determined using HY-8 Version 3.2, a non proprietary software package developed by the Federal Highway Administration and Pennsylvania State University for hydraulic designs of highway culverts.

4.0 FLOODPLAIN MANAGEMENT APPLICATION

The 100-year flood hazard boundaries were delineated on aerial-topographic maps at a scale of 1:4,800 (1" = 400') and a contour interval of 2 feet for the upper West Tributary area. The floodplain delineation determinations for the Sloan Channel area were based on improvement plans with a scale of 1" = 40' and one foot contour interval.

5.0 INSURANCE APPLICATION

5.1 Flood Insurance Zones

Areas within the 100-year flood boundary are termed "Special Flood Hazard Areas (SFHAs)." A 100-year flood refers to a flood level with a 1 percent or greater chance of being equaled or exceeded in any given year. The areas within the 100-year floodplain are further subdivided into insurance risk rate zones. The SFHAs designated in the study area are defined below.

Zone A Special Flood Hazard Areas inundated by the 100-year flood, determined by approximate methods; no base flood elevations determined.

Areas outside the 500-year floodplain and are termed "minimal flood hazard areas." The areas of subject to minimal flood hazard are designated as:

Zone X Areas of minimal flood hazard from the principle source of flood in the area determined to be outside the 500-year floodplain. Flood insurance is available in participating communities but is not required by regulation.

5.2 Flood Insurance Rate Map

Using the results of this FIS, a Flood Insurance Rate Map (FIRM) will be prepared that depicts the SFHAs described in Section 5.0. FEMA publishes the FIRM and distributes it to a wide range of users. Private citizens, community officials, insurance agents and brokers, lending institutions, and Federal agencies use the FIRM to determine the degree of flood hazard in specific areas of the community so

that actuarial premium rates can be assigned and full insurance coverage obtained for properties at risk.

6.0 OTHER STUDIES

This study is intended to update and supersede the portion of the previous FIS that pertains to the study area. The previous controlling study was the "Las Vegas Valley Flood Insurance Study," prepared by James M. Montgomery, Consulting Engineers, Inc. for Clark County Regional Flood Control District, August 1991.

The chief difference from the previous study, is the inclusion of the Confluence Detention Basin. Subbasins have also been subdivided on the West Tributary to provide more detailed flow values at specific locations.

Studies which were reviewed for the incorporation of new improvements, for defining basin characteristics and descriptions, and for developing the hydrology, are listed in the references.

WORK MAP DELINEATION SUMMARY

Clark County, Nevada and Incorporated Areas

FLOOD INSURANCE STUDY RESTUDY

The 100-year flood hazard boundaries were delineated on aerial-topographic maps at a scale of 1:4,800 (1" = 400') and a contour interval of 2 feet for the upper West Tributary area. Cross-section characteristics were verified by field observations

The floodplain delineation determinations for the Sloan Channel area were based on improvement plans with a scale of 1" = 40' and one foot contour interval. There were no flooplain areas determined in the Sloan Channel area - flows were contained within streets or flood control facilities.

I. INTRODUCTION

Post, Buckley, Schuh & Jernigan, Inc. (PBS&J), under contract with the Clark County Regional Flood Control District (CCRFCD), is preparing a Flood Insurance Restudy of the Range Wash, located within the City of North Las Vegas, and Clark County, Nevada. This summary memorandum presents information obtained from field reviews and the data collection and review effort, findings and recommendations for proceeding with the restudy, and a preliminary bibliography.

II. PROJECT DESCRIPTION

Figure 1 shows the approximate limits of the Range Wash study area. **Figure 2** shows a schematic of the Range Wash system. The lower reach of the Range Wash is commonly known as the Sloan Channel. The scope of work for this restudy includes the Western Tributary of the Range Wash and the Sloan Channel. The Eastern Tributary is not included because there is no significant development or present Special Flood Hazard Areas in this area.

The purpose of this restudy is to update the Special Flood Hazard Areas due to two major flood control facilities which reduce the 100-year flow to the Range Wash and Sloan Channel. The two major flood control facilities are the West Range Wash Diversion Dike and the Confluence Detention Basin. There are two areas of Flood Zone "A" which are to be evaluated, and reduced or eliminated, as part of this study.

The West Range Wash Diversion Dike, located near the Grand Teton Drive alignment, is the northern boundary of the study area. The dike has reduced the 100-year flow to the Range Wash by diverting a significant amount of upstream flows to the North Las Vegas Detention Basin. The construction of this facility is expected to impact the Zone "A" upstream of Las Vegas Boulevard. **Figure 3**, a copy of the DFIRMs, Map Numbers 32003 C 1790 D, 32003 C 2180 D and 332003 C 2176D, for Clark County and Incorporated Areas, effective date August 16, 1995, shows the Flood Zones "A" in this area.

The Confluence Detention Basin, presently under construction, is located upstream of the Sloan Channel reach of the Range Wash system and is expected to reduce the 100-year peak flow to the Sloan Channel. Information on the Confluence Detention Basin will be provided in this restudy so that a CLOMR may be obtained. **Figure 4**, a copy of the DFIRM, Map Number 32003 C 2200 D, for Clark County and Incorporated Areas, effective date August 16, 1995, shows the Flood Zones "A" associated with the Sloan Channel.

III. FIELD REVIEW

PBS&J has investigated existing conditions in the field and has prepared a **Photograph Log** included as **Appendix 3**. The photograph log documents the major hydraulic structures and bridges, channel improvements, and natural channels within the Range Wash system. It contains copies of figures from the CCRFCD Master Plan Update (MPU) of the Las Vegas Valley, dated 1991. The MPU figures are provided as an aid to referencing each flood control facility. The MPU labeling system is familiar to local engineers and entities. The MPU shows proposed as well as existing flood control facilities. Only existing facilities are considered in this restudy, with the exception of the Confluence Detention Basin, which is presently under a construction contract.

The log also contains photographs showing flood damage from a 1984 storm in the Vandenberg Channel area.

The photograph log contains the majority of the photographs obtained from the field reconnaissance investigation. A photograph index, included in **Appendix 1** of this memorandum, provides a complete list of each photograph taken, along with its description, MPU facility label, and identification number.

IV. DATA COLLECTION AND REVIEW

Data has been collected and reviewed for the entire study area. Detailed evaluation of hydraulics and facility capacities will focus on eliminated or reducing the Zone "A" Special Flood Hazard Areas. Where there are no present flood hazard areas or evident problems the existing facilities are assumed to have sufficient capacity without further review. Tables included in **Appendix 2** give names of the documents or improvement plans collected to date, and give a brief description of the area and the information that may be useful for this restudy.

V. FINDINGS AND RECOMMENDATIONS

This section presents the data recommended for use in this Range Wash restudy. A description of the data is located in tables found in **Appendix 2.**

Hydrologic Data

After reviewing the hydrologic models obtained, the recent hydrology performed for the Confluence Detention Basin is the most comprehensive, and may be used with modifications such as subdividing particular basins, modeling different storm centerings, and determining whether any recent development may change the land use enough to modify the existing curve numbers. The hydrology for the lower reach of Sloan Channel may be supplemented with hydrologic models prepared for the Hollywood Highlands and Orchards housing developments.

Hydraulic Data

The following is a summary of the information obtained after reviewing the hydraulic models and the improvement plans:

- The G.C. Wallace Sloan Channel 90% Review Plans has recent topography along the existing channel (1995) for hydraulically modeling the Sloan Channel from the Las Vegas Wash Confluence to Stewart Avenue.

- "As-builts" and hydraulic analysis recently completed by G.C. Wallace for the new concrete-lined portion of Sloan Channel from Stewart Avenue to Owens Avenue may be used to reduce flood zones in this area.

- Sloan Channel from Owens Avenue to Lake Mead Boulevard has sufficient capacity, and has been recently been modeled by PBS&J for the Lake Mead/RV Storage project (1995).

- Sloan Channel from Lake Mead Boulevard to Carey Avenue has sufficient capacity. "As-builts" for the Sloan Flood Control Channel Unit 1, by Kercheval & Associates (1982) were reviewed.

- The hydraulic model by Boyle (1993) for the Nellis Air Force Base (NAFB) Golf Course Channel may be used to document diversion to the Confluence Detention Basin.

- The improvement plans and the hydraulic model contained in the Calculations Summary Range Wash/Sloan Channel Confluence Detention Basin, by Boyle (1993)may be used to obtain the CLOMR for the Confluence Detention Basin.

- The channel traversing the NAFB and for the channel extending from the NAFB to Las Vegas Boulevard has sufficient capacity. The Sloan Channel Plan and Profile by James M. Montgomery (1984) were reviewed.

- New 2-ft contour topography for the City of North Las Vegas (CNLV Topo) that is expected to be completed in October, 1995 will be used to model the natural, unlined Range Wash from Las Vegas Boulevard to Lamb Boulevard.

- The hydraulic model (with modifications for the new RCB at Lamb) and topography for the Lamb Industrial Park, by PBS&J (1992) may be used for the natural, unlined Range Wash from Lamb Boulevard to Craig Road.

- Channel plans and CNLV Topo will be used to model the Vandenberg Channel from Craig Road to Lone Mountain Road.

- CNLV Topo will be used to model the natural, unlined Range Wash from Lone Mountain Road to the West Range Diversion Dike

- "As-builts" and the documentation in the Range Wash Sediment Transportation Documentation Notebook (1992, 1993) will be used to document the West Range Wash Diversion Dike

Supplemental Services

The review of the hydrologic, hydraulic, and sediment transport data indicates supplemental services to perform additional work in these areas will not be warranted. PBS&J expects to perform the revisions to hydrology and necessary hydraulic analysis within the allotted budget for floodplain delineation. The Range Wash Sediment Transportation Documentation Notebook is expected to provide sufficient information for the dike to be accepted by FEMA. There remains a possibility FEMA or the TEC may request additional information and analysis.

The CNLV Topo is expected to provide adequate topography for floodplain delineation in the flood hazard areas north of Las Vegas Boulevard. Supplemental Services for aerial survey and mapping will not be required.

Ground surveys are expected to be required to evaluate the un-lined portion of Sloan Channel between Stewart Avenue and Charleston Boulevard. This reach of the channel

is associated with a broad Zone "A" flood hazard area. The un-improved channel is not expected to have sufficient capacity to contain the flows, even with consideration for the Confluence Detention Basin. The area downstream of the detention basin includes an urbanized watershed and runoff from Sunrise and Frenchman Mountains. There is topography available for this reach from the design drawings for Sloan Channel improvements. Field surveys will be required to verify this topography in this critical area. Deposition or maintenance grading may have changed the channel topography. Survey work will also be required to tie in the datum of different sources of topography. Field surveys will also be required to establish cross-sections at critical structures or other limiting cross-section areas. The cost to perform survey work under the Supplemental Services portion of the agreement is not expected to exceed ten thousand dollars ($10,000).

Attention: Mr. William R. Locke, Chief

Supporting Documentation for Review of Hydrologic Changes Resulting from the Construction of the Range Wash Diversion Dike for the City of North Las Vegas

The City of North Las Vegas is proposing the construction of a diversion dike to intercept and divert flows from the Range Wash Drainage Basin. The attached figures depict a schematic view of the dike and its relation to the city. This diversion of flows results in reduced discharges to mapped floodplains within the City of North Las Vegas and results in a reduction of flood hazards to the citizens of North Las Vegas and unincorporated Clark County. Boyle Engineering Corporation, with the assistance of Dr. Richard French, has prepared the attached submittal related to the Diversion Dike.

This submittal is intended to provide information necessary for the review of the diversion dike design. Because the diversion dike is an integral part of changes to the hydrologic system, any changes to the hydrologic model are contingent on review and acceptance of the proposed dike. We have included hydrologic results which illustrate the flow reduction of the dike, however a concurrent study is being completed by another consulting engineering firm which is intended to address the specific hydrologic impacts of the diversion dike. Therefore, no detailed presentation of the hydrology (beyond the pertinent printouts supporting design discharges) is included in this presentation. Once this structure has been reviewed and accepted, a more comprehensive hydrologic submittal will be made.

We are submitting plans and specifications for the diversion dike and a notebook of supporting computations. To expedite FEMA's review, we have identified the various elements required for submittal based on "Data Request Checklist for Conditional Revision to Flood Insurance Study (FIS)/Flood Insurance Rate Map (FIRM) by Conditional Letter of Map Revision (CLOMR)". We will address each item explicitly and comment on where the information can be found if it is relevant to this submittal.

1. This project is being performed for the City of North Las Vegas and the Clark County Regional Flood Control District. The construction of the diversion dike is for public benefit and primarily intended for flood loss reduction to existing development in identified flood hazard areas in the communities of North Las Vegas and Clark County. As indicated in

2. This project involves the construction of a diversion dike across the Range Wash Alluvial Fan. It intercepts flow from the upper portions of the Range Wash Basin and diverts them to an adjacent detention facility. The resulting reduction in downstream discharges reduces flood hazards to existing properties within the City of North Las Vegas and Clark County. Construction plans identifying the alignment and character of the diversion dike are submitted with this application as is a detailed notebook entitled Range Wash Sediment Transport Documentation Notebook which presents the computations used in sizing the diversion dike. Hydrologic impacts have been estimated as part of the design of the diversion dike, however another engineering consultant is preparing detailed hydrologic information as part of revision to the Flood Insurance Study.

3. A letter is attached from the City of North Las Vegas and the Clark County Regional Flood Control District indicating they are sponsoring this design and are requesting FEMA review in accordance with Section 65.4 (B) of the NFIP Regulations.

4-15. The items requested in Sections 4 through 15 relate to the specific revisions to the Community's FIRM map. Because any revisions are subject to changes in the hydrologic model resulting from the construction of the diversion dike, the preparation of this information is premature at this time. Subsequent to the review and acceptance of the diversion dike, a detailed hydrologic evaluation (performed by another engineering consultant) and revisions to the existing community FIRM will be performed. This present submittal is solely intended to solicit comment and acceptance of the diversion dike which is the foundation for changes to the hydrologic system.

16. Construction plans for the diversion dike are submitted herewith.

17. The diversion dike is a levee by FEMA definition and in accordance with Section 65.10 of the NFIP Regulation the following items have been addressed.

    a. A minimum freeboard of 3 feet has been provided in accordance with 65.10 (b) (1). No road bridges or other structures are intended to cross the proposed levee and therefore no additional freeboard has been provided.

       A detailed sediment transport analysis has been performed which identifies the anticipated deposition along the diversion dike alignment. In addition to the 3 feet of freeboard, the total deposition depth has been included in the height of the levee.

       Because water may enter the diversion dike perpendicular to its alignment, an additional freeboard equal to the required velocity head has also been incorporated in the sizing of the dike.

These three freeboard components have been added above the computed water surface depth along the diversion dike. The total dike height of 15.3 feet includes a water depth of 4.4 feet and total freeboard of 10.9 feet. The enclosed notebook entitled Range Wash Sediment Transport Documentation Notebook presents the computations developed in support of the dike sizing. The notebook is extensively annotated and provides a detailed description of its contents.

b. No structures are intended to penetrate the levee.

c. The sediment transport analysis indicates that flow characteristics along the dike will result in deposition prior to reaching equilibrium. As such, no embankment erosion protection is proposed. Should minor anomalies occur in the hydraulic characteristics which result in minor local scour, the size of the dike will limit any possible adverse impacts. As shown on Drawing DT-1 of the plan set, the dike has a top width of 12 feet and slopes of 4:1 and 3:1 at the upstream and downstream faces. At the anticipated design height of 15.3 feet, the width at the toe of the dike will be a minimum of 100 feet. Any localized scour will not compromise the stability of the embankment or the effectiveness of the system.

Because the dike has been evaluated using an equilibrium sediment transport model, no generalized bed or slope scour is anticipated. Therefore, no extraordinary protection measures are required for the embankment.

d. A geotechnical analysis of slope stability has been performed by Converse Consultants Southwest, Inc. and is attached to the submittal in Part 16 of the notebook. This analysis indicates satisfactory factors of safety for slope stability under conditions representing end of construction, sudden drawdown, and static end dynamic steady seepage conditions. In all cases the factor of safety is above those stipulated in "Recommended Guidelines for Safety Inspection of Dams" published by the Corps of Engineers (1973).

e. In the project geotechnical report, Converse estimated that "embankment settlement due to consolidation of fill and foundation materials should be negligible" due to the granular nature of the materials.

f. The alignment of the dike traverses the alluvial fan and will intercept all upstream flows. Downstream flows travel away from the dike and will require no additional drainage.

18-19. This submittal does not relate to frontal dune construction or placement of fill in the floodplain.

20.

a. A detailed sediment transport analysis has been performed which quantifies discharges and volumes of water and sediment associated with the 100-year flood at the dike location. This discharge and associated sediment is slightly higher than the quantities identified at the apex and is more representative of actual conditions to be encountered. The engineering analysis is consistent with the general criteria of FEMA and is documented in the Sediment Transport Documentation Notebook enclosed with this submittal.

b. The enclosed documentation demonstrates that the diversion dike has been designed to accommodate the estimated 100-year peak discharge as well as associated sediment and hydrodynamic and hydrostatic forces.

c. A detailed sediment transport analysis was performed along the dike to identify the impacts of flow along the diversion dike. Because the system is a depositional feature and is at equilibrium subsequent to the deposition, no generalized erosion or scour is anticipated. Any limited localized erosion or scour will not compromise the integrity of the diversion dike since its base width at the toe is in excess of 100 feet.

d. The nature of the diversion dike alignment demands that the facility be designed to withstand discharges impacting the dike perpendicular to its alignment. This impact has been included in the evaluation of the required freeboard as well as in the depth of anticipated deposition.

e. The diversion dike and its associated channel are designed to collect and divert concentrated flood waters and their associated sediment load. This discharge will be conveyed, at approximately equilibrium conditions, along the dike and ultimately into the North Las Vegas Detention Basin. We anticipate no adverse impacts on adjacent properties. All discharges and sediment will be confined to the diversion dike right-of-way or undeveloped federal lands.

f. The engineering analysis used to identify peak discharges and sediment loads along the dike includes runoff from local areas beneath the apex of the alluvial fan.

g. Design and maintenance of the diversion dike will be performed in accordance with the Clark County Regional Flood Control District's Operations and Maintenance Manual. Sedimentation monuments and depth gages will be provided to assist maintenance crews in identifying appropriate maintenance intervals.

All facilities onto which flood waters will be diverted are publically owned. These include the alignment of the diversion dike as well as the downstream North Las Vegas Detention Basin.

h. The City of North Las Vegas and the Clark County Regional Flood Control District have secured the necessary right-of-way for construction as well as permanent easements for the maintenance of these facilities. The downstream terminus of the project is within the North Las Vegas Detention Facility which is owned and operated by the Clark County Regional Flood Control District and the City of North Las Vegas.

We hope this summary assists your review of the attached submittal. We encourage you to call should you have any questions regarding the project scope or the technical content of our submittal. If so, please feel free to call Gerald Simpson, Boyle Project Manager (702) 731-5511 or Mark Glidden, Project Technical Director (303) 987-3443).

CHECKLIST USED IN PROCESSING CONDITIONAL LETTERS OF MAP REVISION (CLOMRs)

Federal Emergency Management Agency

Washington, D.C. 20472

DATA REQUEST CHECKLIST
FOR CONDITIONAL LETTER OF MAP REVISION

Requestor: _____ Case No.: _____

Community: _____ Date: _____

Re: _____

The items checked below in Column 1 are required to process your request for a conditional Letter of Map Revision (LOMR). Items checked in Column 2 have been received and should not be resubmitted unless specifically requested.

(1) Required	(2) Received	
_____	_____	1. Written description of the scope of the proposed project and the methodology used to analyze the project's effects
		2. Hydraulic backwater models of the 100-year flood for the following:
_____	_____	a. Existing conditions (cross sections to reflect conditions prior to construction of the project)
_____	_____	b. Proposed conditions (same cross sections as the existing conditions model, reflecting the proposed project)
		3. Hydraulic backwater models of the 10-, 50-, 100-, and 500-year floods for the following:
_____	_____	a. Duplicate of the effective FIS model
_____	_____	b. Existing conditions (effective FIS model including cross sections through the project site; cross sections should reflect conditions prior to construction of project)
_____	_____	c. Proposed conditions (existing conditions model reflecting the proposed project)
		4. Floodway hydraulic backwater models of the following:
_____	_____	a. Duplicate of effective
_____	_____	b. Existing conditions

(1) Required	(2) Received		
_____	_____	c. Proposed conditions	
_____	_____	5. Copy of the Flood Insurance Rate Map with the project area indicated	
_____	_____	6. Topographic mapping of the entire area covered by the proposed conditions model, indicating the locations of all cross sections used in the hydraulic model and delineating the proposed 100-year floodplain boundary	
		7. Topographic mapping of the entire area covered by the proposed conditions model, indicating the locations of all cross sections used in the hydraulic model and delineating:	
_____	_____	a. The proposed 100- and 500-year floodplain boundaries	
_____	_____	b. The proposed floodway boundary	
_____	_____	8. Other: _____	
		_____	
		_____	
		_____	
		_____	
_____	_____	9. Community acknowledgment of the conditional LOMR request (form enclosed for community's use, if desired)	
		10. Initial fee for conditional LOMR	
_____	_____	a. New bridge or culvert (no channelization)	$420
_____	_____	b. Channel modifications only	$480
_____	_____	c. Channel modification and new bridge or culvert	$630
_____	_____	d. Levees, berms, or other structural measures	$810
_____	_____	e. Structural measures on alluvial fans	$1200

(1) Required	(2) Received	
_____	_____	f. Fee exemption certification in compliance with Section 72.5 of National Flood Insurance Program Regulations

The items checked in Column 1 should be sent within 30 days to the following address:

Federal Emergency Management Agency
Federal Insurance Administration
Office of Risk Assessment
500 C Street, SW., Room 422
Washington, D.C. 20472

Attention: Mr. Charles A. Lindsey

Any initial fee for the request, in the form of a check or money order made payable to the National Flood Insurance Program, should be sent by Registered Mail, Return Receipt Requested. The case number referenced above should be included on the check or money order for identification purposes

DATA REQUEST CHECKLIST FOR CONDITIONAL REVISION TO
FLOOD INSURANCE STUDY (FIS)/FLOOD INSURANCE RATE MAP (FIRM)
BY CONDITIONAL LETTER OF MAP REVISION (CLOMR)

Date: _____

Requestor: _____ Community: _____

Re: _____ Case Number: _____

To help you prepare the required supporting data for your request for a conditional revision, we are enclosing copies of the following:

_____ "National Flood Insurance Program and Related Regulations," dated October 1, 1988

_____ Appeals, Revisions, and Amendments to Flood Insurance Maps, A Guide for Community Officials, dated September 1985

_____ (Other)

The data identified below as "Required" must be submitted for our review. The data identified as "Received" should not be resubmitted. References to the sections of the National Flood Insurance Program (NFIP) regulations that establish specific requirements for supporting data are included as appropriate in the checklist entries. All analyses submitted must be certified by a registered professional engineer. All topographic data submitted must be certified by a registered professional engineer or licensed land surveyor. The meaning of "certification" as it applies to the types of required supporting data is given in Section 65.2(b) of the NFIP regulations.

Description of Data		Required	Received
1. Payment of initial fee for conditional revision according to the following schedule:			
a. New bridge or culvert (no channelization)	$420	_____	_____
b. Channel modifications only	$480	_____	_____
c. Channel modification and new bridge or culvert	$630	_____	_____

Description of Data		Required	Received
d. Levees, berms, or other structural measures	$810		
e. Structural measures on alluvial fans	$1,200		
f. Additional initial fee			

As provided for by Section 72.5 of the NFIP regulations, Federal, State, and local governments and their agencies shall be exempt from the fee requirement for projects they sponsor if the Administrator determines or the requestor certifies that the project is for public benefit and primarily intended for reducing flood losses to existing development, as opposed to planned development, in identified flood hazard areas. If applicable, therefore, a fee exemption certification may be submitted in lieu of the required fee.

The fee or fee exemption certification is to be sent to the following address:

Federal Emergency Management Agency
Federal Insurance Administration
Office of Risk Assessment
Technical Operations Division
500 C. Street, SW., Room 422
Washington, D.C. 20472

Attention: Mr. Charles Lindsey

Payment must be made in the form of a check or money order made payable to the National Flood Insurance Program, and must be sent by Registered Mail, Return Receipt Requested. Please include the case number shown on the first page of this checklist on your check or money order.

2. A concise description of the nature and extent of the requested revision

3. Evidence that the Chief Executive Officer (CEO) of the affected community, or an official designated by the CEO, was asked to submit the request (See Section 65.4 of the NFIP regulations.)

Description of Data	Required	Received
4. A general description of the proposed hydrologic conditions on which the conditional revision request is based (See Section 65.6(c)(1)(i) of the NFIP regulations.)		
5. A general description of the proposed hydraulic conditions, including channel modifications or other projects, on which the conditional revision request is based (See Section 65.6(c)(2)(i) of the NFIP regulations.)		
6. New hydrologic analysis, including a brief description of the methodology used, for the _____ -year flood(s) for _____ (See Section 65.6(a)(7) of the NFIP regulations.)		
7. Evidence that the appropriate local, State, or Federal agency (i.e., _____) has approved the new hydrologic analysis, including the resulting peak discharge values		
8. Printouts (including full input and output listings) from a calibration model, produced by the requestor, that duplicates the hydraulic computer model used to determine the _____ -year water-surface elevations shown for _____ in the effective FIS report and on the effective FIRM (See Section 65.6(a)(8) of the NFIP regulations.) The calibration model may be either the FIS model, reproduced on the requestor's equipment, or a model that yields computed water-surface profiles that duplicate the flood profiles shown for _____ in the effective FIS report.		
9. Printouts (including full input and output listings) from a calibration model, produced by the requestor, that duplicates the hydraulic computer model used to determine the limits of the 100-year floodway shown for _____ on the effective Flood Boundary and Floodway		

Description of Data	Required	Received
Map (FBFM)/FIRM (See Section 65.6(a)(8) of the NFIP regulations.) The calibration model may be either the FIS floodway model, reproduced on the requestor's equipment, or a model that yields the computed floodway widths and water-surface elevations presented in the Floodway Data Table for _____ in the effective FIS report.	_____	_____
10. Printouts (including full input and output listings) from a revised hydraulic model for the _____ -year water-surface elevations on _____. The revised model must be created from the calibration model (Item 8) and must meet the requirement(s) listed below.	_____	_____
____ The model must be based on the same peak discharge values used in the calibration model (Item 8).		
____ The model must be based on the peak discharge values determined in the new hydrologic analysis (Item 6).		
____ The model must account for the effects of the proposed hydraulic conditions on which the conditional revision request is based.		
In addition, the revised model must account for the effects of any encroachments that have occurred in the 100-year floodplain since the FIS hydraulic model was developed and must cover a sufficient length of _____ so that the water-surface elevations computed at cross sections upstream and downstream of the revised reach will match those shown at the same cross sections on the Flood Profiles in the effective FIS report within approximately 0.5 foot. All changes to the input data in the calibration model (Item 8) must be highlighted on the printouts. (See Section 65.6(a)(9) of the NFIP regulations.)		

Description of Data	Required	Received
11. A hydraulic analysis, including a brief description of the methodology used, for the 100-year flood on _____ (See Section 65.6(a)(9) of the NFIP regulations.)	_____	_____
12. Printouts (including full input and output listings) from a revised hydraulic model for the 100-year floodway on _____. The revised model must be created from the calibration model (Item 9) and must meet the requirements listed below.	_____	_____
____ The model must be based on the 100-year peak discharge value(s) used in the calibration model (Item 9).		
____ The model must be based on the 100-year peak discharge value(s) determined in the new hydrologic analysis (Item 6).		
____ The model must account for the effects of the proposed hydraulic conditions on which the conditional revision request is based.		

In addition, the revised model must account for the effects of any encroachments that have occurred in the 100-year floodplain since the FIS floodway model was developed and must cover a sufficient length of _____ so that the water-surface elevations and floodway widths computed at cross sections upstream and downstream of the revised reach will match those shown at the same cross sections on the Flood Profiles and Floodway Data Table in the effective FIS report. The revised model must be based on the equal conveyance reduction method unless agreements have been made with affected property owners that an alternative method would be used. The net effect of the proposed hydraulic conditions, the encroachments that have occurred since the FIS floodway model was developed, and the revised floodway limits must not increase the computed 100-year water-surface elevations by more than 1.0 foot above those computed in the calibration model (Item 8) or those computed in the revised model (Item 10), whichever are lower. (See Section 65.7(b)(4) of the NFIP regulations.)

Description of Data	Required	Received
13. Documentation, as shown below, concerning the approval of the revised floodway (See Sections 65.7(b)(1), (2), and (3) of the NFIP regulations.)	_____	_____
____ Copy of the public notice distributed by the community stating the community's intent to revise the floodway or a statement by the community that it has notified all affected property owners and affected adjacent jurisdictions		
____ Copy of a letter notifying the appropriate State agency of the floodway revision		
____ Documentation of the approval of the revised floodway by the appropriate State agency		
14. Corporate limit map and/or annexation ordinances that reflect the current community boundaries	_____	_____
15. A topographic map that shows the proposed _____ and _____ boundaries, the locations and alignments of all cross sections used in the revised hydraulic models (Items 10 and 12), stream alignments, road alignments, and the community boundaries. The revised _____ and _____ boundaries must tie into those shown on the effective FIRM/FIRM and FBFM upstream and downstream of the revised reach. The scale and topographic definition of the map must be sufficient to provide reasonable accuracy, and the map must be certified by a registered professional engineer. (See Section 65.6(a)(11) and 65.7(b)(5) of the NFIP regulations.)	_____	_____
16. Construction plans, certified by a registered professional engineer, for all project elements, specifically _____ _____ _____.	_____	_____

Description of Data	Required	Received

17. The following data concerning the ability of the _____ proposed to be built along _____ to meet the minimum design and maintenance requirements established for levee systems in Section 65.10 of the NFIP regulations:

a. **Freeboard** -- Evidence which shows that the levee(s) will meet the minimum freeboard require-ments set forth in Section 65.10(b)(1) of the NFIP regulations _____ _____

b. **Closures** -- Evidence which shows that all drainage structures that will penetrate the levee(s) will be fitted with closure devices that will be (1) structural parts of the levee(s) during operation and (2) are designed according to sound engineering practice, as set forth in Section 65.10(b)(2) of the NFIP regulations _____ _____

c. **Embankment Protection** -- An engineering analysis which demonstrates that no appreciable erosion of the levee embankment(s) can be expected during the 100-year flood. The analysis must be performed according to the guidelines set forth in Section 65.10(b)(3) of the NFIP regulations. _____ _____

d. **Stability** -- An engineering analysis that evaluates the stability of the levee embankment(s) and foundation(s). The analysis must be performed according to the guidelines set forth in Section 65.10(b)(4) of the NFIP regulations. _____ _____

e. **Settlement** -- An engineering analysis that assesses the potential for and magnitude of losses of freeboard that may result from settlement of the levee(s) and that demonstrates that the minimum required freeboard will be maintained. The analysis must be performed according to the guidelines set forth in Section 65.10(b)(5) of the NFIP regulations. _____ _____

Description of Data	Required	Received
f. **Interior Drainage** -- An engineering analysis of the potential hazards associated with floodwaters that originate on the landward side of the levee(s) and that would be prevented by the levee(s) from flowing into _____. The analysis must be performed according to the guidelines set forth in Section 65.10(b)(6) of the NFIP regulations.	_____	_____

Description of Data	Required	Received
18. Data which show that any primary frontal dune (as defined in Section 59.1 of the NFIP regulations) that is to be considered an effective barrier to the 100-year flood surge and associated wave action is either a natural dune or an artificial (designed and constructed) dune that is well established and has long standing vegetative cover. It must also be shown that the cross sectional area of the portion of the dune seaward of the dune crest, measured perpendicular to the shoreline above the 100-year stillwater elevation, is greater than 540 square feet. As an alternative to the data described above, authoritative historical documentation may be submitted which shows that the primary frontal dune at a specific site has withstood previous 100-year storm surges and associated wave action. (See Section 65.11 of the NFIP regulations.)	_____	_____
19. The following data concerning the proposed placement of fill in the [100-year floodplain of _____, where no regulatory floodway has been established/regulatory floodway of _____], which we have determined could cause a rise in the computed 100-year water-surface elevations greater than that allowed by Section 60.3 [(c)(10)/(d)(3)] (See Section 65.12 of the NFIP regulations.):		
a. Community Request — A request from the affected community for the Federal Emergency Management Agency's conditional approval of the proposed change, accompanied by the appropriate initial fee or a request for an exemption from the fee, whichever is appropriate. (See Item 1 of this checklist.)	_____	_____
b. Evaluation of Alternatives — An evaluation of alternative actions that would not result in a rise in the computed 100-year water-surface elevations greater than that allowed by Section 60.3 [(c)(10)/(d)(3)]. The evaluation must demonstrate that the alternatives are not feasible.	_____	_____

Description of Data	Required	Received
c. *Legal Notice* -- Documentation of individual legal notice to all property owners affected by the proposed action, both within and outside the community, that explains the effect of the proposed action on their properties.	_____	_____
d. Concurrence of Other Communities -- Evidence that the CEOs of other communities affected by the proposed action concur in that action.	_____	_____
e. Certification Concerning Structures — Certification that no structures are in the areas that will be affected by the increased 100-year water-surface elevations.	_____	_____
f. Flood Elevation Revision Request — A request for a revision to the existing computed 100-year water-surface elevations, submitted according to the procedures outlined in Section 65.6 of the NFIP regulations. The required technical supporting data are listed as Items _____ of this checklist.	_____	_____
g. Floodway Revision Request — A request for a revision to the regulatory floodway, submitted according to the procedures outlined in Section 65.7 of the NFIP regulations. The required technical supporting data are listed as Items _____ of this checklist.	_____	_____
20. The following data concerning the effect of _____ on the alluvial fan Special Flood Hazard Area:		
a. Engineering analyses that quantify the design discharges and the volumes of water, debris, and sediment associated with the 100-year flood at the apex of the fan under current watershed conditions and under potential adverse conditions (e.g., deforestation of the watershed by fire). The potential for debris flow and sediment movement must		

Description of Data	Required	Received
be assessed with an engineering method acceptable to the Federal Emergency Management Agency. The assessment should consider the characteristics and availability of sediment in the drainage basin above the apex and on the alluvial fan.		
b. Engineering analyses which show that _____ will accommodate the estimated 100-year peak discharge, consisting of the total volume of water, debris, and sediment determined in Item a. above, and the associated hydrodynamic and hydrostatic forces.		
c. Engineering analyses which show that _____ has/have been designed to withstand the potential erosion and scour forces.		
d. Engineering analyses or evidence which shows that _____ will provide protection against flows that migrate or suddenly move to the project site from other portions of the fan.		
e. Engineering analysis that assesses the methods by which concentrated floodwater and the associated sediment load will be disposed of and the effect of those methods on adjacent properties.		
f. Engineering analyses which demonstrate that flooding from local runoff, or sources other than the fan apex, will be insignificant or will otherwise be accommodated by appropriate flood control or drainage measures.		
g. Evidence that the effect of _____ on flood hazards in all areas of the fan (including those not protected by _____) and the design and maintenance requirements for the various elements of _____ were reviewed and approved by the community, State, or local agency that has jurisdiction over flood control activities in the community.		

Description of Data	Required	Received
b. Assurance from the community that appropriate easements have been secured from those who own property onto which flood waters will be diverted.		

1. SUMMARY MEMORANDUM

WEST RANGE WASH DIVERSION DIKE

SEDIMENT TRANSPORT ANALYSIS AND DIKE SIZING CRITERIA

SUMMARY MEMORANDUM

INTRODUCTION

The West Range Wash Diversion Dike is intended to intercept and divert flows from the headwaters of the western tributary of Range Wash and direct them to the North Las Vegas Detention Basin. Construction drawings for this facility are attached hereto for your information and review. The dike alignment which traverses the West Range Wash alluvial fan was established in a previous project undertaken by Boyle for the City of North Las Vegas (1991 Facility Planning Study). The efforts presented in the present study were undertaken to determine an appropriate dike height which satisfies the design requirements stipulated by FEMA. These requirements include consideration of depth of flow, scour or deposition potential, hydrostatic and hydrodynamic head, flooding depth and appropriate freeboard for the 100-year peak flow.

The methodologies and results presented in this report follow the general procedures proposed in the Memorandum of Understanding (MOU) dated September 27, 1991 (See Part 2. Memorandum of Understanding). Changes in the selected methodologies have been made only where required to develop information which was previously assumed to be available from other sources. Boyle Engineering Corporation and Dr. Richard French have worked closely on the formulation and execution of the approaches presented herein. A comprehensive Design Notebook containing the calculations, graphs and computer output has been produced and is attached hereto for review. Various sections of the Design Notebook are referenced herein.

The major steps utilized in the dike design are summarized below:

- o Review Hydrology
- o Determine Average Annual Sediment Yield
- o Compute Event Specific Yield
  - Inflow Sediment Load
  - Fan Equilibrium Flow Using Dawdy/FEMA
  - Integrate to Verify Average Annual Yield
- o Model Fan/Dike System
  - HEC-6/Yang
  - Alluvial Fan Transport
  - Dike Equilibrium Transport
  - Transition Section
  - Deposition/Scour Evaluation
- o Water Surface Profile
  - HEC-2
  - Profile with Deposition/Scour
- o Dike Height Determination

HYDROLOGY

The hydrology utilized in this evaluation is consistent with the revised Flood Insurance Study hydrology recently developed for the 1991 Flood Control Master Plan Update of the Las Vegas Valley undertaken by the Clark County Regional Flood Control District (CCRFCD). The Flood Insurance Study hydrologic model for the Range Wash Basin was based on a computer model developed by Boyle as part of their Facility Planning Study. Because the construction of the West Range Wash Diversion Dike is imminent, the FIS hydrologic model recognizes the existence of the dike (i.e., those portions of the Range Wash basin below the diversion dike are

included in the FIS model of the lower basin). The flows diverted by the dike will discharge into the North Las Vegas detention basin and do not impact any floodplains other than the obvious reduction of flow in the lower Range Wash basin.

A baseline model of the watershed above the dike was developed to estimate dike design flows. The modeling methodology and basic assumptions are consistent with those in the *Flood Insurance Study*. A *100-year peak discharge of 7,028 cfs was used in this analysis (Note* this is approximately 10% higher than noted in the 1991 CCRFCD Master Plan). Other recurrence intervals were also simulated for use in this analysis including the 2, 5, 10, 25, and 50-year events. Peak flows and total hydrographs have been developed for each. (See Part 3. Hydrology in the Design Notebook).

AVERAGE ANNUAL SEDIMENT YIELD

The average annual sediment yield at the apex of the fan is the starting point for all subsequent sediment transport evaluations of the Range Wash systems. The MOU indicates that the average annual yield will be used as the basis for the estimation of 2, 5, 10, 25, 50, and 100-year event yield since no specific estimates were available within the Range Wash Basin which related yield to a recorded discharge. It was concluded that a reliable estimate of average annual sediment yield could be developed and used for the development of specific event yields. For this evaluation the PSIA Methodology was used to estimate sediment yield at the dike location. The details of this methodology are presented in the 1991 Facilities Planning Study and are included in Part 4. Ave. Annual Yield of the Design Notebook. The average annual yield value calculated for the West Tributary of Range Wash was 16 AF (0.4 AF/Sq. Mi/Yr). This was compared to regional estimates developed by the Corps of Engineers in their Las Vegas Valley Feasibility Study. There was good correlation with the COE range of 0.3 to 0.5 AF/Sq. Mi/Yr. *Consequently, an average annual sediment yield at the dike location of 16* AF was used.

EVENT SPECIFIC YIELD

The approach utilized in developing event specific yields differed somewhat from that proposed in the MOU. A defensible relationship between the 100-year event yield and the average annual sediment yield could not be identified after a review of the available literature. Various values of the relationship between 100-year event yield and the average annual yield were identified in the literature but none could be transferred directly to the Range Wash basin. As a result, it was necessary to undertake an iterative process to determine the sediment yield from the 100-year event. The process began with the estimation of the equilibrium sediment transport down the alluvial fan surface for various recurrence intervals. These values were then integrated to establish an average annual sediment yield based on the fan's ability to deliver sediment. This yield estimate was compared to the PSIA estimate of average annual sediment yield. When both estimates matched, the individual event yield was assumed to be correct and was used for future analyses and ultimately to size the dike. The following paragraph describes this process in greater detail.

The HEC-6 computer program was used to simulate sediment transport through the entire fan/dike system. Yang's formulation of sediment transport equations presented in HEC-6 was used to compute transport capacity. An article published in the Journal of Hydraulic Engineering (Comparisons of Selected Bed-Material Load Formulas, Yang and Wan; ASCE 117(8), 973-989) compares several sediment transport equations for various sediment concentrations, slopes and Froude numbers. For conditions similar to those encountered along the dike (steep slopes and Froude numbers near one), Yang's formulation was determined to provide the best results when compared to measured results. Yang's methodology is commonly accepted, as demonstrated by its inclusion in HEC-6, and appears to be the most appropriate formulation for application on Range Wash (See Part 5. Yang Paper in Design Notebook.)

The process of establishing the event specific yield required several key assumptions which had to be tested. A critical assumption was the determination of material size distributions for both the inflowing sediment load generated in the basin above the apex and the fan surface materials. Eight surface samples were taken on the alluvial fan to estimate the particle sizes to be used as the bed material distribution in the transport model. This particle size distribution could not be used as inflow to the system since no fine materials were found on the alluvial fan surface and yet the upstream watershed provides an abundant source of fine particles which are washed through the system. To estimate the fine particle portion of the total sediment load, samples from the valley floor further downstream in the Las Vegas Wash system were used. (See Part 6. Particle Size Distribution).

Critical assumptions were evaluated during this calibration and integration process to determine their sensitivity and reasonableness. These variables included the roughness coefficient, the inflow sediment volume estimate, the temperature of the inflow, and the particle size distribution of the inflowing materials. The results of the sensitivity analysis indicate that the estimate of average annual yield as a function of each specific yield was relatively insensitive to minor changes in variables with the exception of the percentage of fine particles in the inflow. The final percentage of fine particles, those less than 0.064 millimeters, was 38% and compared favorably with particle size distribution of materials farther downstream in the Las Vegas Valley.

The description of channel cross section geometry in HEC-6 requires a fixed channel bank. The channel bed may move vertically (scour and deposition), but no lateral changes in cross-section are possible. The Dawdy/FEMA assumption (Flood Frequency Estimates on Alluvial Fans, ASCE Journal of the Hydraulics Division, 105(11), 1407-1413) for alluvial fan flooding was used in this study. This assumption establishes a channel geometry on an alluvial fan which is a function of discharge (See Part 7. Fan Geometry). Because HEC-6 does not allow for lateral changes in the channel cross-section, it was necessary to run the fan model with a constant

cross section. Therefore, a series of constant discharges and fixed cross sections were modeled to establish alluvial fan flow characteristics and equilibrium sediment transport. For the 100-year peak example see the Design Notebook Part 8. Fan Equilibrium. The model was tested against hand computations for simple verification (See Part 9. Model Confirmation).

The equilibrium sediment transport values for each discharge were aggregated into an event hydrograph and a total sediment volume for each event was determined. The individual event sediment yield estimates were integrated to determine an average annual sediment yield for comparison to the previously computed PSIA methodology estimate of average annual sediment yield. This integration was performed by plotting a curve of total sediment yield for each event against the probability of the event recurrence and determining the area beneath the curve which represents average annual sediment yield. (See Part 10. Ave. Annual Yield in Design Notebook).

FAN/DIKE SYSTEM ANALYSIS

The previously described hydrograph and event specific sediment inflow was used to evaluate the effects of the West Range Wash Dike system on the sediment transport of the 100-year event. HEC-6 requires that a hydrograph and a sediment rating curve be input into the model as a boundary condition. The sediment yield rating curve was developed based on the fan equilibrium transport capacity computations used to develop the event specific yield estimates described above.

The HEC-6 model began at the apex of the alluvial fan with the apex flow hydrograph and an assumed sediment load. (See Part 11. System Model). Flows down the alluvial fan were modeled using the previously described channel of constant cross-section. Flows were modeled down the fan where they reached equilibrium and were eventually intercepted by the West Range Wash Dike. The model cross-section was modified to reflect the geometry of the channel along the upstream toe of the dike and the slope along the dike as it traverses the fan.

A 120 foot wide unlined channel with 3:1 side slopes was assumed along the upstream toe of the dike. Two longitudinal bed slopes were simulated which represented the extremes of the conditions encountered along the dike. (0.5 percent and 1.0 percent).

HEC-6 determines the equilibrium sediment transport down the fan and, based on a comparison with the computed equilibrium sediment transport along the dike, the total volume of deposition is computed for each time step. Because of intermediate computational instabilities, it was not possible to determine the total volume of deposition which occurred at the peak flow by interpreting HEC-6 directly. An intermediate computation based on a mass curve of sediment transport was required which determined that 37% of the total deposition occurred at the peak discharge. (See Part 12. Deposition Percentage).

HEC-6 computes equilibrium transport at each cross-section and cannot distribute deposition through a channel reach. The methodology presented in "Design of Small Dams" U.S. Department of the Interior, Bureau of Reclamation, 1977, for evaluating the geometry and longitudinal length of a scour hole was modified slightly and applied here to estimate the length of deposition and the maximum depth of the deposited materials at the 100-yr peak flow (See Part 13. Transition Model). This methodology was compared to a parabolic vertical curve of a comparable length and resulted in a good correlation for the maximum depth. A transition length of approximately 1,100 feet and a depth of deposition of 5.6 feet was computed.

WATER SURFACE PROFILE DETERMINATION

The computed transition and deposition were incorporated into a HEC-2 run to determine the water surface through the transition section. A horizontal transition between the rectangular Dawdy/FEMA cross-section on the fan and the trapezoidal cross-section of the channel along the dike was assumed to occur over the length of the vertical transition. The HEC-2 model was used to compute a water surface profile for the 100-year peak flow. (See Part 14. Water-Surface Profile in Design Notebook).

DIKE HEIGHT DETERMINATION

Dike height is a combination of several factors. The depth of deposition was determined from the previously described deposition computations. The water surface was determined from the HEC-2 simulation. A hydrodynamic head (flow impacting the dike perpendicular to its alignment) was determined by computing the total energy head for flows down the fan and for flows along the dike and using the larger of the two values. Freeboard is three (3) feet. See Part 15 of Design Notebook for explanation of final dike height determination.

The total dike height is therefore:

Deposition	5.6 feet
Depth of Flow	4.6 feet
Velocity Head	2.3 feet
Freeboard	3.0 feet
Total	15.3 feet

2. MEMORANDUM OF UNDERSTANDING AND OTHER CORRESPONDENCE

MEMORANDUM OF UNDERSTANDING

AND OTHER CORRESPONDENCE

This Memorandum of Understanding was prepared on September 24, 1991. Boyle presented our scope of work to the Clark County Regional Flood Control District and the City of North Las Vegas. In some cases changes were required to reflect additional data needs or due to necessary refinements resulting from the level of detail of available data. These differences are discussed in greater detail in the appropriate section.

The memorandum of understanding was transmitted, along with a cover letter to Mr. Alan Johnson of the Federal Emergency Management Agency. The intent was to solicit FEMA's comments regarding the proposed scope and the applicability of those methodologies. FEMA responded on October 22, 1992 with a letter indicating that they did not have jurisdiction to review our methodology or to comment on our approach. Subsequent communication between the Regional Flood Control District, City of North Las Vegas and FEMA have convinced FEMA authorities that the proposed diversion dike construction does impact mapped floodplains and therefore will be reviewed. This correspondence is enclosed for review.

MEMORANDUM OF UNDERSTANDING

September 24, 1991

MEMORANDUM

TO: City of North Las Vegas
Clark County Regional Flood Control District

FROM: Boyle Engineering Corporation

SUBJECT: **West Range Wash Diversion Dike**
Evaluation and Design Methodologies
Memorandum of Understanding

INTRODUCTION

The methodologies proposed for the design of the West Range Wash Diversion Dike are presented in this Memorandum of Understanding. They address the technical aspects of hydrologic, hydraulic and sediment analyses and Federal Emergency Management Agency (FEMA) Regulations. They are based on our experience with the Range Wash Facility Plan, with various projects in the Las Vegas Valley and with the FEMA requirements regarding facilities on alluvial fans. We have also enlisted the consultation and support of Dr. Richard French to assist with some of the more complex alluvial fan issues.

This project has been discussed with FEMA on several occasions and with representatives of Baker Engineers. While this site is not in a mapped A Zone or in any mapped flood hazard area, the City of North Las Vegas and Boyle recognize the potential alluvial flooding hazard. The design of these facilities is intended to meet the requirements for a Letter Of Map Revision.

Regardless of the approaches developed, that coordination between the City of North Las Vegas, CCRFCD and Boyle will be an important component of the project. This is likely to expedite the reviews and approvals by FEMA. To accomplish this, frequent and on-going dialogue among the project participants and FEMA is anticipated.

DESIGN CONCEPT

The general concept of the Range Wash Diversion Dike is to intercept flows on the alluvial fan and convey them in a controlled fashion to the North Las Vegas Detention Basin. Because of the probablistic nature of alluvial fan flooding, the design discharge will be the full 100-year apex discharge along the entire diversion dike alignment. This should result in a stable conveyance facility with adequate freeboard to meet FEMA's requirements and which will require minimum maintenance to remain functional.

FEMA has indicated that this design concept is consistent with their desire to adopt basin wide control measures. We have also obtained the FEMA check list for review of Conditional Letters of Map Revision (CLOMR) and intend to address the expressed items.

FACILITY PLAN ASSUMPTIONS

The alignment and sizing of the diversion dike presented in the Range Wash Facility Plan is based on the conveyance of the peak 100-year apex discharge. The average annual sediment yield was converted to a 100-year sediment volume and distributed throughout the runoff hydrograph assuming a linear relationship to hydrograph flows. The diversion dike alignment was established to maintain a slope, which in combination with an upstream channel, was capable of conveying flows consistent with the Dawdy/FEMA regime concept. The depth of flow was computed using the channel size and slope and was adjusted using a bulking factor to account for sediment.

The height of the dike was then determined by adding the dynamic head (energy head) plus three feet of channel freeboard to the computed flow depth plus bulking factor adjustment. A soil cement lining was proposed for the upstream face and was extended into native materials as protection against scour.

CHANNEL ALIGNMENT

The channel alignment identified in the facilities plan is the starting point for the final design effort. The identified alignment has a consistent slope of 0.8 percent across the fan. The approach which will be utilized in the final design will be to minimize adjustments to the dike alignment and refine the channel geometry as necessary to achieve a stable design. If it is not possible to maintain equilibrium along the proposed alignment, changes in the channel alignment will be evaluated.

HYDROLOGY

Final design will use the Flood Insurance Study hydrologic evaluations prepared for CCRFCD. The 100-year peak apex discharge and volume will be used.

SEDIMENT YIELD

The final design will utilize the results of the Pacific Southwest Interagency Committee (PSIAC) method analysis performed for the Facility Plan. For FEMA's benefit, a comparison of the PSIAC method estimates and those of other studies will be provided.

The annual yield estimated by the PSIAC method will be converted to an event yield using factors developed in conjunction with Dr. Richard French. The conversion of these values will be appropriately documented with references to technical literature and past reports.

A particle size distribution of the sediment yield will be developed by taking surface sediment samples on the alluvial fan. These alluvial fan surface materials were deposited during alluvial flooding events and should represent the sediment load being carried to the fan. The particle size distribution will be developed by taking three surface samples within a 20-foot radius and mixing them to develop one composite sample. The sample will include gravel or cobble materials if present on the surface. These samples will be taken at five sites across the fan.

To relate the total sediment load to a specific event hydrograph, the total volume will distributed through the hydrograph by using a linear relation to actual flow. In this way, a actual hydrograph representing both instantaneous discharge and sediment delivery can be developed.

TRANSPORT

We propose to utilize a steady state routing model to evaluate the sediment transport capacity of the channel adjacent to the diversion dike. Adjustments will then be made to the cross section geometry or the dike alignment to result in a stable conveyance.

The 100-year hydrograph representing both discharge and sediment will be the basis of design. The upstream boundary condition for the sediment transport analysis will be assumed to be the entire inflow hydrograph. Once a design is established, the facilities will be evaluated using a 10-year event to identify potential concerns regarding operation and maintenance.

Bed material site distribution and cross section geometry are input variables for the transport model. The cross section geometry is defined based on the preliminary designs provided in the Facility Plan. Bed material will be based on the existing materials along the dike alignment. The bed material particle size distribution will be determined by taking samples along the alignment at the surface, three feet below the surface and six feet below the existing ground surface. These will then be used to develop the actual bed material particle size distribution with the channel in place. Sampling will be performed at ten sites along the dike alignment.

The model used to estimate transport capacity will be based on Yang's formulation for total bed material transport. Based on a recent article in the Journal of Hydraulic Engineering, it appears that Yang's formulation is most accurate at predicting sediment transport for steep slopes (S > .5%) in sandy soils and with Froude numbers in the range of .5 to 4.0. For FEMA's benefit, we will also compare the results of those predicted by HEC-6.

The inflow hydrograph will be routed through the channel along the diversion dike in 15 minute time increments to establish sediment transport capacity and changes in channel geometry and invert elevation. The cross section geometry will be refined to achieve equilibrium sediment transport. If required, changes in alignment will be made to adjust the slope and thereby transport capacity.

This information will define the potential for deposition and scour along the length of the dike. This information, in combination with computed water surface elevations, will establish the levee height necessary to convey the 100-year event.

TOTAL DIKE HEIGHT

In addition to the diversion dike height necessary to convey the flow and account for potential deposition, FEMA requires that three feet of freeboard be provided. In addition, the hydrodynamic head must be included in the determination of overall height. The energy head of the flow approaching the dike in a perpendicular direction will be added. The velocity and cross section of flow down the fan will be based on the assumptions provided by the Dawdy/FEMA regime equation.

STRUCTURAL INTEGRITY

The upstream face of the West Range Wash Diversion Dike will be lined with soil cement paving. This will protect the embankment against scour or erosion and will provide a factor of safety against seepage through the embankment. The soil cement lining will extend from the top of the levee down to the invert and will be embedded beneath the invert and the estimated scour depth.

A stability analysis will be performed for the dike cross section. The stability analysis will include static saturated conditions, rapid drawdown conditions, and a seismic event. The computed factor of safety will be somewhat conservative since the upstream lining will provide protection against embankment saturation and the transient nature of flood flows will further reduce the risk of saturation.

Provisions will be made to accommodate potential settlement based on the results of a geotechnical analysis. The recommendations provided by the geotechnical engineer with regard to compaction requirements and potential long-term settlement will be incorporated.

SUBMITTAL TO FEMA

The results of the analysis and design performed on the West Range Wash Diversion Dike will be submitted to FEMA in a manner consistent with their check list for Conditional Revision to Flood Insurance Study (FIS)/Flood Insurance Rate Map (FIRM) by Conditional Letter of Map Revision (CLOMR). While this form is not appropriate at the present time since no existing FIS or FIRM exists, it will facilitate FEMA review and will provide the City of North Las Vegas and CCRFCD with a greater level of comfort that the facilities will ultimately be accepted by FEMA. No assurances can be made that the facilities will meet the long-term requirements of the flood insurance program. In fact, the understanding of alluvial fan hydraulics and flood hazard is not great. It is possible that as FEMA's understanding improves, changes in the existing requirements maybe proposed and may affect the regulatory benefit realized by the diversion dike. Regardless of the regulatory status of the diversion dike, it will provide a tangible benefit to downstream properties by collecting and diverting uncontrolled alluvial fan discharges from the upper watershed away from potentially developable areas and into the North Las Vegas Detention Basin.

RE: WEST RANGE WASH DIVERSION DIKE

Dear Mr. Gilpin:

Transmitted herewith is correspondence received from the Federal Emergency Management Agency (FEMA) regarding their role in reviewing the design of the West Range Wash Diversion Project. FEMA has reconsidered their role in the review of this project. More specifically, FEMA will review an application for a Conditional Letter of Map Revision (CLOMR) because the project will impact Special Flood Hazard Areas (SFHA). The hydrologic impacts to SFHA is stated in the reported titled "Las Vegas Valley Flood Insurance Study Hydrology Report," dated September 1991, by James M. Montgomery.

Important in FEMA's letter is that they will consider waiving the review fees for a CLOMR since the project will protect existing development. I understand both the City of North Las Vegas and Clark County, the affected communities, would need to request the review fees be waived.

Boyle Engineering has supplied a draft of the estimated fees to prepare and submit a CLOMR. I would suggest that we meet to discuss the work required for the CLOMR submittal.

Sincerely,

GALE WM. FRASER, II, P.E.
Assistant General Manager

RETURN RECEIPT REQUESTED

Mr. Gale Wm. Fraser, II, P.E.
Assistant General Manager
Clark County Regional Flood Control District
301 E. Clark Avenue, Suite 301
Las Vegas, Nevada 89101

Dear Mr. Fraser:

This is to acknowledge receipt of your January 15, 1992, letter regarding the proposed West Range Wash Diversion Dike project and to confirm information discussed with you at the February 25, 1992, meeting and by telephone on March 10, 1992. Your letter was in reply to our October 22, 1991, letter to Mr. Mark Glidden, Boyle Engineering. We had informed Mr. Glidden that because the West Range Wash Diversion Dike project was not located in an identified Special Flood Hazard Area (SFHA), we would not review this project. In your letter, you requested that we reconsider our role in reviewing this project because of the impact that it will have on identified flood hazards in the City of North Las Vegas and in the Unincorporated Areas of Clark County, Nevada.

As discussed during the February 25, 1992, meeting with you, we will review this project because of its impact on existing SFHAs. We were informed at this meeting that Boyle Engineering would prepare the data required for a Conditional Letter of Map Revision (CLOMR). In addition, we also discussed the possibility of waiving the review fees for this project. During a telephone conversation on March 10, 1992, between you and a representative of our Technical Evaluation Contractor, it was confirmed that the data necessary to process a CLOMR for this project will be submitted and that upon receipt of these data, we will initiate a review. It was also verified that if the purpose of this project is primarily to protect existing development, then the affected communities would request that the review fees be waived.

We appreciate the opportunity to work with you so that the Flood Insurance Rate Maps for communities in Clark County reflect the best available flood risk information.

If you have any questions regarding this request, please call Mr. Karl Mohr of my staff in Washington, DC, at (202) 646-2770.

Sincerely,

William R. Locke
Chief, Risk Studies Division
Federal Insurance Administration

West Range Wash Diversion Dike
50 Percent plans and Sediment Transport Analysis

Dear Mr. Gilpin:

I have completed my review of the referenced documents received February 11, 1992. Our meeting on February 18, 1992 was very informative and demonstrated that Boyle Engineering is properly addressing the key issues of sediment transport analysis relative to design considerations and acceptance of the design by FEMA. During recent discussions with Karl Mohr with FEMA's Washington office it was suggested that in order to receive FEMA's attention in reviewing and accepting this project design, it may be necessary to formally apply for a Conditional Letter of Map Revision (CLOMR). Mr. Mohr expressed FEMA's budgetary reluctance to review this project without such an application.

A CLOMR application can be pursued at any time at the City of North Las Vegas' direction. We may want to have a meeting to coordinate this effort prior to expending any time or resources. The CLOMR application must state that this project is a public flood control facility being undertaken to reduce flood impacts to existing residential structures. Identifying the project purpose as such will preclude payment of review fees in association with the CLOMR. Furthermore, the CLOMR application should be submitted as data to support the expected reduced flow rates caused by the project to aid FEMA's current review of the FIS Hydrology Report. If this approach fails to receive FEMA's attention, the CLOMR may have to identify an actual change to a specific floodplain caused by the project.

301 E. Clark Avenue, Suite 301 • Las Vegas, Nevada 89101
(702) 455-3139 • FAX: (702) 455-3870

The District does not have any comments to offer at this time with regard to the contents of the plans or sediment transport analysis. As discussed in our meeting, the final edition of the sediment transport analysis should have a complete narrative and report format to be suitable for submittal to FEMA at the appropriate time. The project is physically straight forward. The plans will be reviewed for constructability and completeness at the 90 percent submittal of the plans and special provisions.

Please be aware that $4,000,000 is programmed on the Bond Project List for the construction of this project. Recent discussions with you indicate that this will be sufficient for construction of the entire project as it is presently designed. As discussed in our meeting, it may be worthwhile to peruse participation of Nellis construction forces to further reduce the cost of the project. As the project development nears solicitation of construction funding from the District, please note the following requirements:

a) Revised cost estimate;

b) Approved 90 percent plans and specifications;

c) Proof of right of entry for construction; BLM applications are proceeding on schedule as we have discussed;

d) Proof that all applicable federal, state and local permits have been obtained;

e) Project presentation agenda item; and

f) Interlocal contract agenda item.

If you should have any questions or if I can be of any assistance, please give me a call.

VIRGINIA BAX-VALENTINE, P.E.

Mr. William R. Locke
Chief of Risk Studies Division
Federal Insurance Administration
Federal Emergency Management Agency
500 C Street S.W.
Washington, D.C. 20472

Dear Mr. Locke:

The District is implementing flood control projects that will provide 100-year flood protection to the residences within the District. Some projects are not located in Federal Emergency Management Agency (FEMA) designated Special Flood Hazard Areas (SFHA), but all projects have some affect on downstream SFHA. The West Range Wash Diversion Dike project is one of the projects, not located in a SFHA, that will have a dramatic affect in reducing flood flows in SFHA along the Range Wash system in the northeast portion of the Las Vegas Valley. This project is being funded by the District, project management is being provided by the City of North Las Vegas and the design is being performed by Boyle Engineering Corporation (Boyle).

The report titled Clark County Regional Flood Control District, Las Vegas Valley Flood Insurance Study Hydrology Report (FIS Report), which has been previously transmitted to FEMA and will be the hydrologic documentation to guide flood insurance restudy efforts within the Las Vegas Valley, demonstrates the effects the West Range Wash Diversion Dike will have on downstream SFHA. A comparison of Table 2-2 (without West Range Wash Diversion) and Table 2-3 (with West Range Wash Diversion) in the FIS Report demonstrates the effectiveness of the project in reducing the 100-year discharges at downstream locations. The following values were obtained from the FIS Report:

	100-Year Discharge	
Location	Table 2-2 w/o diversion	Table 2-3 w/diversion
West. Trib. @ Carey (Node G1)	7,719 cfs	3,900 cfs
Main Channel @ Owens 7774(Node S)	7,876 cfs	5,200 cfs

301 E. Clark Avenue, Suite 301 • Las Vegas, Nevada 89101
(702) 455-3129 • FAX (702) 455-3258

The District understands that Boyle has requested FEMA to provide review comments during the design of the project and that FEMA responded, based upon FEMA's limited resources and budgetary constraints, that FEMA can only comment on flood control projects that affect designated SFHA. The above information from the FIS Report demonstrates the effects this project will have on designated SFHA. The District, when the project is completed and a restudy of the SFHA on the Range Wash is performed, will take into account the flood reducing capabilities of the project on the Range Wash. It may be that Boyle over simplified the flood reduction aspects the project will have on the Range Wash and its associated SFHA when requesting review by FEMA.

I respectfully request that FEMA reconsider their role in the review of this project as the design progresses. This request is made on behalf of the City of North Las Vegas and is further emphasized by the correspondence transmitted herewith. Review by FEMA at this time would greatly facilitate future restudy efforts on the Range Wash.

Sincerely,

Gale Wm. Fraser, II, P.E.
Assistant General Manager

301 E. Clark Avenue, Ste. 300
Las Vegas, NV 89101

Dear Gale:

You have received a letter from Mark Glidden of Boyle Engineering dated December 20, 1991 (enclosed). The letter is a "response to FEMA's Jurisdiction Determination" on the Range Wash Diversion Dike. FEMA has indicated that it doesn't have the time or inclination to review the proposed design of the diversion dike.

As you know, the dike is a critical element of future F.I.S. amendments proposed for the eastern portion of Las Vegas Valley. It appears that because FEMA and the CCRFCD are partners in the F.I.S. amendments, FEMA could be influenced to at least preliminary review the design concept and issue a threshold approval. It will be beneficial to all concerned governmental agencies especially Clark County and North Las Vegas and will greatly facilitate the F.I.S. amendment process.

It would be appreciated if the CCRFCD would act on the City's behalf and contact Mr. William R. Locke, Chief of the Risk Studies Division for the Flood Insurance Administration in an attempt to convince him of the importance of a design concept approval.

Mr. Glidden and City staff members are available to discuss this issue at any level including a visit to Mr. Locke's office in Washington D.C. if necessary.

Thank you for your consideration in this matter.

Very truly yours,

John L. Murchie
Adm. of Development & Flood Control

Response to FEMA Jurisdiction Determination

On October 22, 1991 Mr. William R. Locke, Chief of the Risk Studies Division for the Federal Insurance Administration sent Mark Glidden a letter responding to Boyle's request for review comments on the Memorandum of Understanding for the West Range Wash Diversion Dike Project. In this letter, Mr. Locke states"...projects to reduce flood hazards that are not identified on National Flood Insurance Program (NFIP) maps are not under our purview. Considering our limited resources and budgetary constraints, we can only comment on flood-control projects that affect designated Special Flood Hazard Areas."

Their response references our Memorandum of Understanding, transmitted with the letter of September 27, 1991, in which we indicate that the Diversion Dike is not in a designated Special Flood Hazard Area, however it does cross what appears to be an alluvial fan which is certainly of considerable interest to FEMA. It appears that our over simplification of the impacts of the West Range Wash Diversion Dike may have misled FEMA into believing that the facilities would not have an impact of identified flood hazards.

In reviewing the existing Flood Insurance Rate Maps for the City of North Las Vegas, Nevada dated December 15, 1983 and those for Clark County dated September 29, 1989, it is clear that the West Range Wash Diversion Dike does in fact reduce flood hazards along areas identified by the National Flood Insurance Program. In fact, the Vandenberg Channel and adjacent facilities, as identified on community panel number 320007 0004 C of the City of North Las Vegas Flood Insurance Rate Map, would be impacted by the diversion of alluvial fan flows. Facilities identified on the Clark County Flood Insurance Rate Map panels 320003 1025 B and 320003 1250 B are also impacted. They include the Vandenberg Channel and the Sloan Channel through unincorporated Clark County.

The purpose of the West Range Wash Diversion Dike is to divert flow generated in the mountainous regions north of the City of Las Vegas and prevent them from reaching the more developed areas of the City as well as those areas of unincorporated Clark County. Our Range Wash Facility Plan indicates that the Dike achieves this purpose and results in a reduction in the identified flood hazard area as shown on the National Flood Insurance Rate Maps. The Clark

County Regional Flood Control District has recognized these benefits. They have instructed their consultant performing the hydrologic study for the Flood Insurance Study update to incorporate the impacts of the Dike into their modeling effort. Therefore, FEMA may be forced to recognize and evaluate the impacts of the Diversion Dike when reviewing the Flood Insurance Study Hydrologic Evaluation.

The West Range Wash Diversion Dike is an integral, and critical, part of the facilities proposed to control flooding in the Range Wash Basin and to protect the citizens of North Las Vegas and Clark County. The impacts of this entire system, including the Dike, will eventually be included in a submittal to FEMA requesting a Map Revision. Given the cost and importance of the Dike to this overall system, we consider it critical that FEMA enter into formal consultations regarding the hydrologic, hydraulic, alluvial fan and sediment transport issues used to design the alignment, slope and capacity of this facility at the earliest possible time.

Hopefully this letter will provide you with ample support and justification to ask FEMA to reconsider their determination that a review of our proposed methodologies and the resulting facilities is beyond their purview. If we can provide you with any additional information please do not hesitate to contact us.

Dear Mr. Glidden:

With your letter dated September 27, 1991, to Mr. Alan A. Johnson of my staff, you enclosed a Memorandum of Understanding with the City of North Las Vegas and the Clark County Regional Flood Control District. The memorandum presents the methodologies that Boyle Engineering Corporation is proposing for the design of the West Range Wash Diversion Dike. You asked that we review the memorandum and inform you of whether the approaches and methodologies proposed are consistent with our requirements.

The memorandum states that the project site is not in a mapped A Zone or in any mapped flood hazard area. Although we appreciate your efforts to coordinate with us during the initial stages of the proposed project, projects to reduce flood hazards that are not identified on National Flood Insurance Program (NFIP) maps are not under our purview. Considering our limited resources and budgetary constraints, we can only comment on flood-control projects that affect designated Special Flood Hazard Areas.

Although we cannot provide the review you requested, we are available to answer any questions you may have about the NFIP in general. If we can assist you in that manner, please call Mr. Karl F. Mohr of my staff at (202) 646-2770.

Sincerely,

William R. Locke

Proposed Methodologies for West Range Wash Diversion Dike Design

Over the past several months we have spoken to you on several occasions regarding a project being proposed within the City of North Las Vegas. This project involves drainage facilities to protect portions of the City of North Las Vegas from flows generated within the Range Wash Drainage Basin. Headwaters of the western tributary of Range Wash are in a mountainous area and flows discharge onto what appears to be an alluvial fan. The City retained Boyle Engineering Corporation to prepare a Facilities Planning Study to identify facilities which address flooding within the Range Wash Basin. During the course of this study several discussions were held with FEMA.

After evaluating the findings presented in the facilities plan, the City has elected to proceed with the design of a diversion dike which collects flows from the alluvial fan and conveys them to an existing storm water detention facility. The diversion dike enables the City to take advantage of excess capacity in the storm water detention facility and, through control of flows across the alluvial fan, protects downstream properties from flood damage. This approach is consistent with FEMA's objective of providing fan wide control of flooding in areas subjected to alluvial fan flows.

Boyle recognizes the importance of proceeding with a sound technical approach which is consistent with FEMA's guidelines and expectations. We also understand the importance of on-going communication with FEMA and FEMA's Study Contractor to minimize potential misunderstandings and delays. It is our hope that through these on-going communications, the final submittal of the Diversion Dike Design and supporting calculations will be more complete and comprehensive and reduce the effort required by FEMA and their Study Contractor for review. Toward this end, we are enclosing with this letter a Memorandum of Understanding with the City of North Las Vegas and the Clark County Regional Flood Control District presenting our approach to the evaluation and design methodologies for the Diversion Dike.

This Memorandum of Understanding presents our proposed approach to the evaluation of the alluvial fan hydrology, hydraulics and sediment transport as well as our approach to the physical design of the facilities. As you will note, our approach is comprehensive and will focus on what we understand to be the critical areas of interest to FEMA. During the course of the project we anticipate discussing our findings on a regular basis with you or your Study Contractor.

While we recognize that it is difficult to comment on an approach without a comprehensive understanding of the issues and concerns within the watershed, we request that you inform us if some of the approaches or methodologies proposed are inconsistent with the latest FEMA requirements. Any input you could provide us at this time regarding the reasonableness of our proposed approach will be greatly appreciated.

Thank you very much for taking the time to provide us with your insight into FEMA's technical and regulatory requirements. We look forward to having the opportunity to discuss this project with you in more detail in the near future. Should you have any questions regarding this project or any of the specific elements of the project, please feel free to contact Mark Glidden in our Denver office (303) 987-3443 or Walter Hines in our Las Vegas office (702) 731-5511.

MEMORANDUM

TO: City of North Las Vegas
Clark County Regional Flood Control District

FROM: Boyle Engineering Corporation

SUBJECT: **West Range Wash Diversion Dike**
Evaluation and Design Methodologies
Memorandum of Understanding

INTRODUCTION

The methodologies proposed for the design of the West Range Wash Diversion Dike are presented in this Memorandum of Understanding. They address the technical aspects of hydrologic, hydraulic and sediment analyses and Federal Emergency Management Agency (FEMA) Regulations. They are based on our experience with the Range Wash Facility Plan, with various projects in the Las Vegas Valley and with the FEMA requirements regarding facilities on alluvial fans. We have also enlisted the consultation and support of Dr. Richard French to assist with some of the more complex alluvial fan issues.

This project has been discussed with FEMA on several occasions and with representatives of Baker Engineers. While this site is not in a mapped A Zone or in any mapped flood hazard area, the City of North Las Vegas and Boyle recognize the potential alluvial flooding hazard. The design of these facilities is intended to meet the requirements for a Letter Of Map Revision.

Regardless of the approaches developed, that coordination between the City of North Las Vegas, CCRFCD and Boyle will be an important component of the project. This is likely to expedite the reviews and approvals by FEMA. To accomplish this, frequent and on-going dialogue among the project participants and FEMA is anticipated.

DESIGN CONCEPT

The general concept of the Range Wash Diversion Dike is to intercept flows on the alluvial fan and convey them in a controlled fashion to the North Las Vegas Detention Basin. Because of the probablistic nature of alluvial fan flooding, the design discharge will be the full 100-year apex discharge along the entire diversion dike alignment. This should result in a stable conveyance facility with adequate freeboard to meet FEMA's requirements and which will require minimum maintenance to remain functional.

FEMA has indicated that this design concept is consistent with their desire to adopt basin wide control measures. We have also obtained the FEMA check list for review of Conditional Letters of Map Revision (CLOMR) and intend to address the expressed items.

FACILITY PLAN ASSUMPTIONS

The alignment and sizing of the diversion dike presented in the Range Wash Facility Plan is based on the conveyance of the peak 100-year apex discharge. The average annual sediment yield was converted to a 100-year sediment volume and distributed throughout the runoff hydrograph assuming a linear relationship to hydrograph flows. The diversion dike alignment was established to maintain a slope, which in combination with an upstream channel, was capable of conveying flows consistent with the Dawdy/FEMA regime concept. The depth of flow was computed using the channel size and slope and was adjusted using a bulking factor to account for sediment.

The height of the dike was then determined by adding the dynamic head (energy head) plus three feet of channel freeboard to the computed flow depth plus bulking factor adjustment. A soil cement lining was proposed for the upstream face and was extended into native materials as protection against scour.

CHANNEL ALIGNMENT

The channel alignment identified in the facilities plan is the starting point for the final design effort. The identified alignment has a consistent slope of 0.8 percent across the fan. The approach which will be utilized in the final design will be to minimize adjustments to the dike alignment and refine the channel geometry as necessary to achieve a stable design. If it is not possible to maintain equilibrium along the proposed alignment, changes in the channel alignment will be evaluated.

HYDROLOGY

Final design will use the Flood Insurance Study hydrologic evaluations prepared for CCRFCD. The 100-year peak apex discharge and volume will be used.

SEDIMENT YIELD

The final design will utilize the results of the Pacific Southwest Interagency Committee (PSIAC) method analysis performed for the Facility Plan. For FEMA's benefit, a comparison of the PSIAC method estimates and those of other studies will be provided.

The annual yield estimated by the PSIAC method will be converted to an event yield using factors developed in conjunction with Dr. Richard French. The conversion of these values will be appropriately documented with references to technical literature and past reports.

A particle size distribution of the sediment yield will be developed by taking surface sediment samples on the alluvial fan. These alluvial fan surface materials were deposited during alluvial flooding events and should represent the sediment load being carried to the fan. The particle size distribution will be developed by taking three surface samples within a 20-foot radius and mixing them to develop one composite sample. The sample will include gravel or cobble materials if present on the surface. These samples will be taken at five sites across the fan.

To relate the total sediment load to a specific event hydrograph, the total volume will distributed through the hydrograph by using a linear relation to actual flow. In this way, a actual hydrograph representing both instantaneous discharge and sediment delivery can be developed.

TRANSPORT

We propose to utilize a steady state routing model to evaluate the sediment transport capacity of the channel adjacent to the diversion dike. Adjustments will then be made to the cross section geometry or the dike alignment to result in a stable conveyance.

The 100-year hydrograph representing both discharge and sediment will be the basis of design. The upstream boundary condition for the sediment transport analysis will be assumed to be the entire inflow hydrograph. Once a design is established, the facilities will be evaluated using a 10-year event to identify potential concerns regarding operation and maintenance.

Bed material site distribution and cross section geometry are input variables for the transport model. The cross section geometry is defined based on the preliminary designs provided in the Facility Plan. Bed material will be based on the existing materials along the dike alignment. The bed material particle size distribution will be determined by taking samples along the alignment at the surface, three feet below the surface and six feet below the existing ground surface. These will then be used to develop the actual bed material particle size distribution with the channel in place. Sampling will be performed at ten sites along the dike alignment.

The model used to estimate transport capacity will be based on Yang's formulation for total bed material transport. Based on a recent article in the Journal of Hydraulic Engineering, it appears that Yang's formulation is most accurate at predicting sediment transport for steep slopes (S > .5%) in sandy soils and with Froude numbers in the range of .5 to 4.0. For FEMA's benefit, we will also compare the results of those predicted by HEC-6.

The inflow hydrograph will be routed through the channel along the diversion dike in 15 minute time increments to establish sediment transport capacity and changes in channel geometry and invert elevation. The cross section geometry will be refined to achieve equilibrium sediment transport. If required, changes in alignment will be made to adjust the slope and thereby transport capacity.

This information will define the potential for deposition and scour along the length of the dike. This information, in combination with computed water surface elevations, will establish the levee height necessary to convey the 100-year event.

TOTAL DIKE HEIGHT

In addition to the diversion dike height necessary to convey the flow and account for potential deposition, FEMA requires that three feet of freeboard be provided. In addition, the hydrodynamic head must be included in the determination of overall height. The energy head of the flow approaching the dike in a perpendicular direction will be added. The velocity and cross section of flow down the fan will be based on the assumptions provided by the Dawdy/FEMA regime equation.

STRUCTURAL INTEGRITY

The upstream face of the West Range Wash Diversion Dike will be lined with soil cement paving. This will protect the embankment against scour or erosion and will provide a factor of safety against seepage through the embankment. The soil cement lining will extend from the top of the levee down to the invert and will be embedded beneath the invert and the estimated scour depth.

A stability analysis will be performed for the dike cross section. The stability analysis will include static saturated conditions, rapid drawdown conditions, and a seismic event. The computed factor of safety will be somewhat conservative since the upstream lining will provide protection against embankment saturation and the transient nature of flood flows will further reduce the risk of saturation.

Provisions will be made to accommodate potential settlement based on the results of a geotechnical analysis. The recommendations provided by the geotechnical engineer with regard to compaction requirements and potential long-term settlement will be incorporated.

SUBMITTAL TO FEMA

The results of the analysis and design performed on the West Range Wash Diversion Dike will be submitted to FEMA in a manner consistent with their check list for Conditional Revision to Flood Insurance Study (FIS)/Flood Insurance Rate Map (FIRM) by Conditional Letter of Map Revision (CLOMR). While this form is not appropriate at the present time since no existing FIS or FIRM exists, it will facilitate FEMA review and will provide the City of North Las Vegas and CCRFCD with a greater level of comfort that the facilities will ultimately be accepted by FEMA. No assurances can be made that the facilities will meet the long-term requirements of the flood insurance program. In fact, the understanding of alluvial fan hydraulics and flood hazard is not great. It is possible that as FEMA's understanding improves, changes in the existing requirements maybe proposed and may affect the regulatory benefit realized by the diversion dike. Regardless of the regulatory status of the diversion dike, it will provide a tangible benefit to downstream properties by collecting and diverting uncontrolled alluvial fan discharges from the upper watershed away from potentially developable areas and into the North Las Vegas Detention Basin.

cc: Dr. Richard French

rangewas/n0730010/memo912

3. HYDROLOGY

HYDROLOGY

The basis for the hydrology used in sizing the diversion dike was a model developed by James M. Montgomery (JMM) Consulting Engineers for the Clark County Regional Flood Control District. This model was used both for the Regional Flood Control District's Master Plan Update and for the Flood Insurance Study revision being undertaken currently. The particular model used was one for the Range Wash Basin and included all watersheds above Range Wash's confluence with the Las Vegas Wash.

The model utilized is a HEC-1 model which combines the SCS dimensionless unit hydrograph simulation for undeveloped basins and kinematic wave simulation for developed watersheds. Routing is accomplished using the Muskingam method or kinematic wave. Rainfall was developed using the information contained in the Clark County Regional Flood Control District's Drainage Design Manual and past studies.

The HEC-1 model used to identify the discharges along the proposed diversion dike is a modified version of the JMM Model. The dike was superimposed on the model and those basins tributary to the dike were modeled separately. Modifications to drainage basin area for those subbasins traversed by the dike were made. In addition, a depth area reduction factor reflecting the total tributary area above the dike was used to adjust point rainfall depths. This revised model is included in the packet as is JMM's original HEC-1 model for the entire Range Wash Basin. For comparative purposes the HEC-1 model developed by JMM for the basins below the dike is included. A summary of the hydrographs used for the design of the Range Wash Diversion Dike is included in this section.

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRU
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSI
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

```

```

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HEC-1 MODEL

UPDATED VERSION

RANGE WASH BASIN

ABOVE DIKE

100-YR

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HEC-1 MODEL

UPDATED VERSION

RANGE WASH BASIN

ABOVE DIKE

50-YR

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HEC-1 MODEL

UPDATED VERSION

RANGE WASH BASIN

ABOVE DIKE

25-YR

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HEC-1 MODEL

UPDATED VERSION

RANGE WASH BASIN

ABOVE DIKE

10-YR

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HEC-1 MODEL

UPDATED VERSION

RANGE WASH BASIN

ABOVE DIKE

5-YR

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

HEC-1 MODEL

UPDATED VERSION

RANGE WASH BASIN

ABOVE DIKE

2-YR

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

4. AVERAGE ANNUAL YIELD

AVERAGE ANNUAL SEDIMENT YIELD

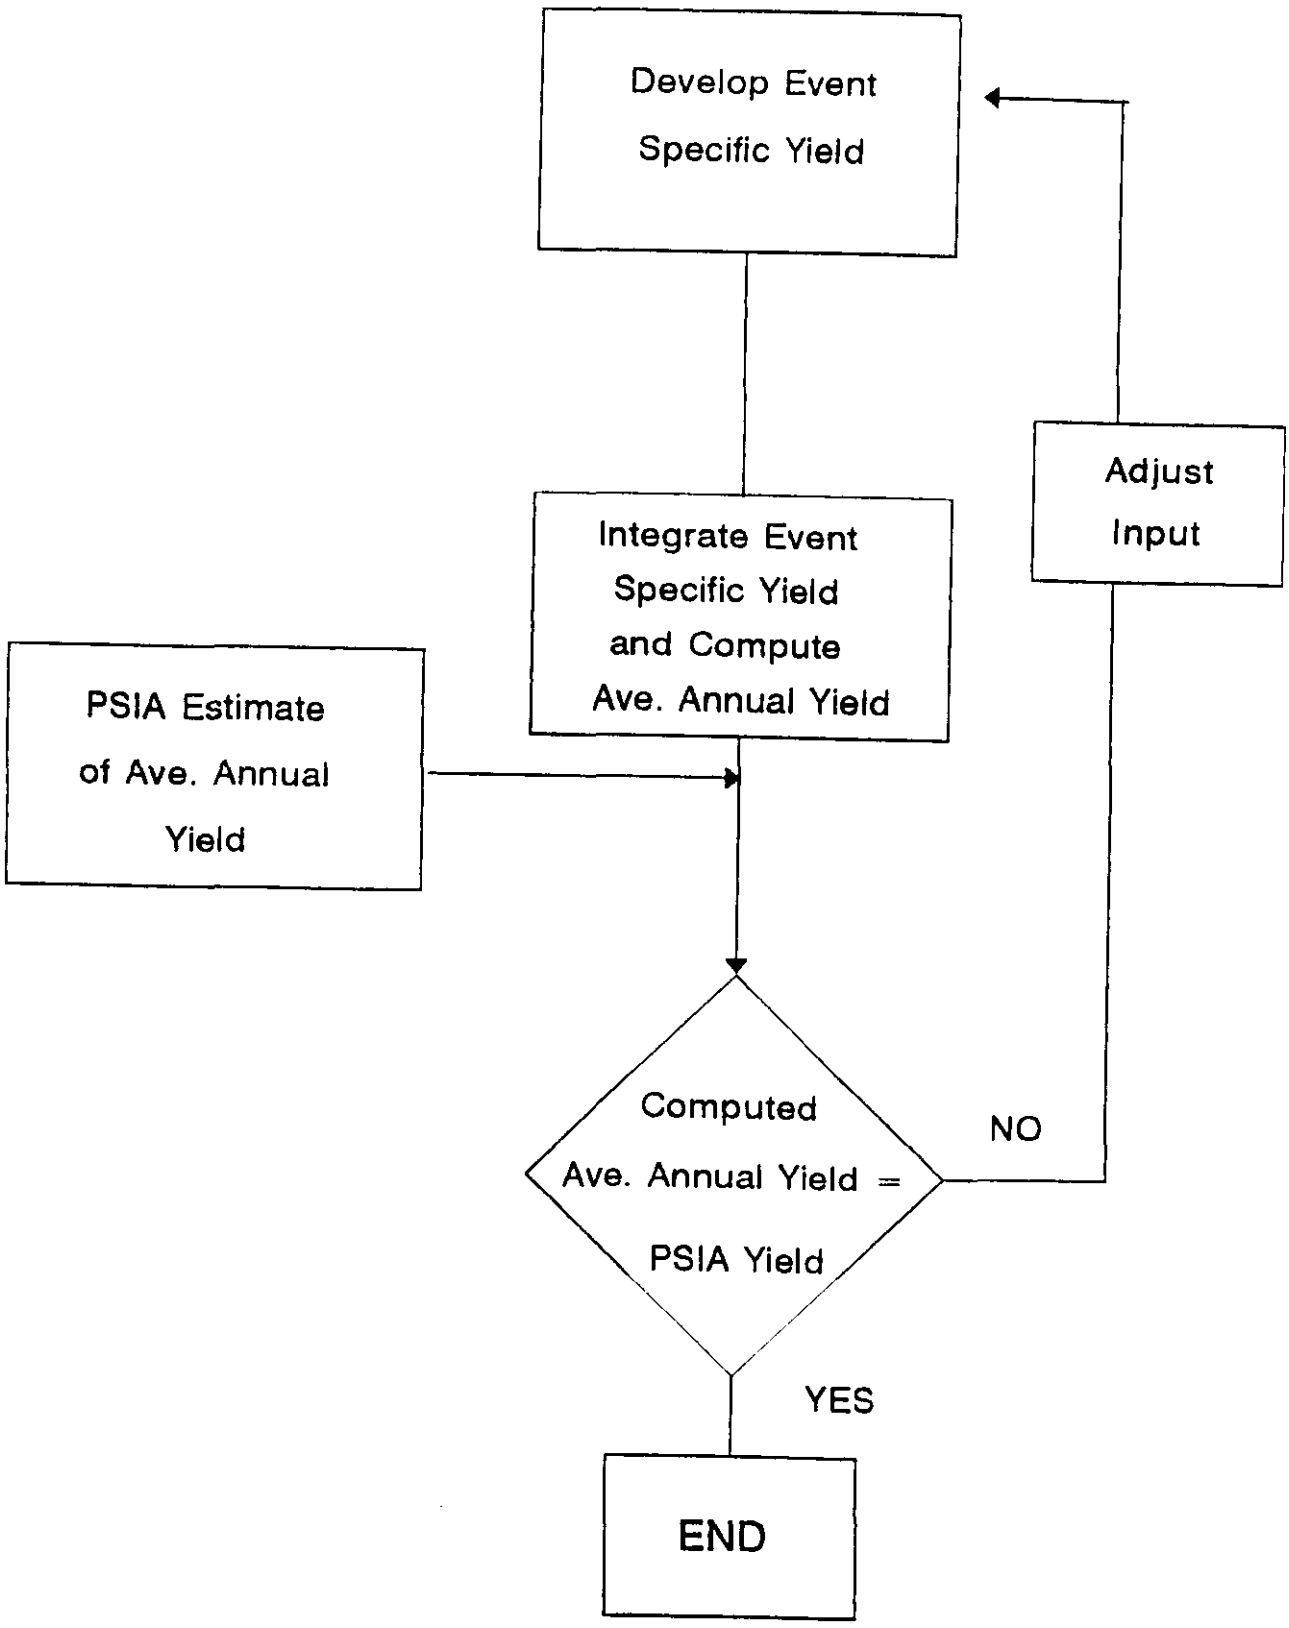
The foundation for the estimate of average annual sediment yield is the work prepared for the 1991 Facility Planning Study. In this report, prepared by Boyle Engineering Corporation, an estimate of average annual sediment yield was developed using the Pacific Southwest Interagency (PSI) Methodology. This methodology has been applied successfully to watersheds throughout the southwestern United States and was deemed most appropriate for the Range Wash Area. In addition, the information necessary to develop an estimate using PSI is easily derived from available sources or field observations. A copy of the sediment yield section from the Facilities Planning Study, and a copy of the Pacific Southwest Interagency Committees presentation of the PSI methodology is included.

The results developed for the Facilities Planning Study were compared to the Corps of Engineers Feasibility Study for the Las Vegas Valley. In this report, the COE estimated a range of an average annual yield for the Range Wash Basin between 0.3 and 0.5 AF/square mile/year. They also provided a graphic which relates drainage basin area to average annual sediment yield. The estimates for the eastern and western tributaries of Range Wash are plotted on this curve and demonstrate that Boyle's estimates from the Facilities Planning Study are slightly higher but well within the margin of error of the COE's study.

As previously mentioned, the foundation for subsequent estimates of sediment yield by event is the average annual sediment yield. Boyle's initial intended approach was to identify a relationship between average annual yield and event specific yield through a review of the published literature. After reviewing several references, reports, and published articles, it

become clear that no defensible relationship could be identified which could be applied to the Range Wash basin. As such, a deviation from the memorandum of understanding was necessary.

Boyle adopted an approach which estimated a yield for a series of specific events and integrated the yield versus probability relationship to arrive at an average annual estimate. This estimate of average annual yield was compared to the PSI estimate of average annual yield. Adjustments in the assumptions used to develop the event specific yields were made as required. When the two estimates matched, it was assumed that the event specific yields represented sediment yield from the Range Wash basin.



Develop Event Specific Yield
Adjust Input
Integrate Event Specific Yield and Compute Ave. Annual Yield

SEDIMENT YIELD ANALYSIS - 1991 FACILITIES PLAN

From 1991 Facility Planning Study

SEDIMENT YIELD ANALYSIS

Methodology

The sediment yield analysis of the Range Wash Study Area was performed using the Pacific Southwest Interagency (PSIA) methodology. This methodology is intended for broad planning purposes rather than specific project planning. The PSIA methodology considers climate and physical factors of the area, as well as evidence of past erosion, to determine a sediment yield classification for the area in question. The factors consideration: geology, soils, climate, runoff, topography, ground cover, land use, upland erosion, and channel erosion and sediment transport. The factors are each assigned a numeric value based on information obtained from a rating which is used to estimate unit sediment yield.

Basin Discretization

Three watershed subdivisions were selected for analysis using the PSIA methodology: Western Range Wash tributary to the detention facility identified in the master plan (Node F of the Hydrologic analysis); Eastern Range Wash tributary to the detention facility identified in the master plan (Node P1 of the Hydrologic analysis), and; both Washes above their confluence Node M of the Hydrologic analysis).

Factors Affecting Sediment Yield

The sediment yield analysis factors are summarized below:

Surface Geology: The exposed rock of the study area is predominantly limestone and dolomite, somewhat fractured and weathered. Rock is only exposed in the steep upland areas.

Soils: Soils of the area are generally very gravely with a distinct erosion pavement. Soil material is fine sandy loam with occasional caliche layers and high percentage of rock fragments. A larger extent of caliche was found near the surface in the Eastern Range Wash area than in the western area.

Climate: The Las Vegas Valley has an arid climate with infrequent convective storms and little freeze-thaw occurrence.

Runoff: The Range Wash watersheds produce moderate runoff peak flows and volumes.

Topography: The steep upland slopes have high relief with extensive alluvial fan development at their base. A larger percentage of the western tributary has steep slopes than of the eastern tributary.

Ground Cover: Vegetative ground cover is less than 20 percent. An extensive erosion pavement of rock fragments covers most of the study area.

Land Uses: The majority of the study area is virtually undisturbed except for occasional roads, and mining exploration.

Upland Erosion: The erosion pavement is evidence of upland erosion as are the numerous rills and gullies on the alluvial fans.

Channel Erosion and Sediment Transport: Eroding channel backs are evident where flow is collected either naturally or by man caused means (e.g., roads). Flow is intermittent and of short duration. The eastern tributary is channelized to a slightly higher degree than the western tributary area. The fan above the western ponding area has no well defined channel.

Results

The factors described above were assigned a numeric value representing their relative contribution to the sediment yield of the part of the basin in question. These numeric values were summed and a rating was established. Using curves provided by the PSIA methodology, a unit sediment yield was estimated.

Table II-8 presents a summary of the numeric values assigned to each analysis factor and an estimate of the total average annual sediment production which can be expected at each point of interest.

TABLE II-8

SEDIMENT YIELD ANALYSIS SUMMARY

	Western Tributary	Eastern Tributary	Confluence
PSIA Factor Ratings			
Geology	2	2	2
Soils	7	5	6
Climate	2	2	2
Runoff	5	5	5
Topography	11	8	6
Ground Cover	3	3	3
Land Use	-10	-10	-10
Upland Erosion	12	10	10
Channel Condition	10	18	15
Summary Ratings	42	43	38
Unit Sediment Yield (af/sq mi/yr)	.40	.42	.37
Drainage Area (sq mi)	41	40	133
Sediment Yield			
Estimated Average Annual Sediment Yield (af/yr)	16	17	49

Comparisons with Past Studies

The average annual sediment yield for the three watershed subdivisions is estimated to range from 0.37 af/sq.mi./yr to 0.42 af/sq.mi./yr. The COE feasibility study developed, and presented, a curve of estimated average annual sediment delivery rates to detention basins within the Las Vegas Valley. These curves present sediment delivery per year per square mile versus basin area for areas similar to those found in Range Wash. The COE Feasibility Study estimates were 0.35 af/sq.mi./yr to 0.40 af/sq.mi./yr. This is very close to the values determined in this effort. Differences may be attributed to slightly higher rainfall in the Range Wash watershed than in the Valley as a whole.

SELECTION AND EVALUATION OF MEASURES FOR REDUCTION OF EROSION AND SEDIMENT YIELD

October 1968

FACTORS AFFECTING SEDIMENT YIELD IN THE PACIFIC SOUTHWEST AREA

Recommendations of the Water Management Subcommittee
Sedimentation Task Force, PSIAC
October 1968

Introduction

The material that follows is suggested for use in the evaluation of sediment yield in the Pacific Southwest. It is intended as an aid to the estimation of sediment yield for the variety of conditions encountered in this area.

The classifications and companion guide material are intended for broad planning purposes only, rather than for specific projects where more intensive investigations of sediment yield would be required. For these purposes it is recommended that map delineations be for areas no smaller than 10 square miles.

It is suggested that actual measurements of sediment yield be used to the fullest extent possible. This descriptive material and the related numerical evaluation system would best serve its purpose as a means of delineating boundaries between sediment yield areas and in extrapolation of existing data to areas where none is available.

This may involve a plotting of known sediment yield data on work maps. Prepared materials such as geologic and soil maps, topographic, climatic, vegetative type and other references would be used as aids in delineation of boundaries separating yield classifications. A study of the general relationships between known sediment yield rates and the watershed conditions that produce them would be of substantial benefit in projecting data to areas without information.

Sediment Yield Classification

It is recommended that sediment yields in the Pacific Southweat area be divided into five classes of average annual yield in acre-feet per square mile. These are as follows:

Classification	1	$>$ 3.0	acre-feet/square mile
	2	1.0 - 3.0	" "
	3	0.5 - 1.0	" "
	4	0.2 - 0.5	" "
	5	$<$ 0.2	" "

Nine factors are recommended for consideration in determining the sediment yield classification. These are geology, soils, climate, runoff, topography, ground cover, land use, upland erosion, and channel erosion and sediment transport.

Although only the high, moderate and low sediment yield levels are shown on the attached table, interpolation between these levels may be made.

Surface Geology

Over much of the southwest area, the effect of surface geology on erosion is readily apparent. The weaker and softer rocks are more easily eroded and generally yield more sediment than do the harder more resistant types. Sandstones and similar coarse-textured rocks that disintegrate to form permeable soils erode less than shales and related mudstones and siltstones under the same conditions of precipitation. On the other hand, because of the absence of cementing agents in some soils derived from sandstone, large storms may produce some of the highest sediment yields known.

The widely distributed marine shales, such as the Mancos and shale members of the Moenkopi Formation, constitute a group of highly erodible formations. The very large areal extent of the shales and their outwash deposits gives them a rank of special importance in relation to erosion. Few of the shale areas are free from erosion. Occasionally, because of slope or cover conditions, metamorphic rocks and highly fractured and deeply weathered granites and granodiorites produce high sediment yield. Limestone and volcanic outcrop areas are among the most stable found within the western lands. The principal reason for this appears to be the excellent infiltration characteristics, which allow most precipitation to percolate into the underlying rock.

In some areas all geologic formations are covered with alluvial or colluvial material which may have no relation to the underlying geology. In such areas the geologic factor would have no influence and should be assigned a value of 0 in the rating.

Soils

Soil formation in the Pacific Southwest generally has not had climatic conditions conducive to rapid development. Therefore, the soils are in an immature stage of development and consist essentially of physically weathered rock materials. The presence of sodium carbonate (black alkali) in a soil tends to cause the soil particles to disperse and renders such a soil susceptible to erosion.

There are essentially three inorganic properties--sand, silt, and clay--which may in any combination give soil its physical characteristics. Organic substances plus clay provide the binding material which tends to hold the soil separates together and form aggregates. Aggregate formation and stability of these aggregates are the resistant properties of soil against erosion. Unstable aggregates or single grain soil materials can be very erodible.

Snow appears to have a minor effect on upland slope erosion since raindrop impact is absent and runoff associated with snow melt is generally in resistant mountain systems.

Frontal storms in which periods of moderate to high intensity precipitation occur can produce the highest sediment yields within the Southwest. In humid and subhumid areas the impact of frontal storms on sediment may be greatest on upland slopes and unstable geologic areas where slides and other downhill soil movement can readily occur.

Convective thunderstorm activity in the Southwest has its greatest influence on erosion and sedimentation in Arizona and New Mexico and portions of the adjoining states. High rainfall intensities on low density cover or easily dispersed soils produces high sediment yields. The average annual sediment yield is usually kept within moderate bounds by infrequent occurrence of thunderstorms in any one locality.

High runoff of rare frequency may cause an impact on average annual sediment yield for a long period of time in a watershed that is sensitive to erosion, or it may have little effect in an insensitive watershed. For example, sediment that has been collecting in the bottom of a canyon and on side slopes for many years of low and moderate flows may be swept out during the rare event, creating a large change in the indicated sediment yield rate for the period of record.

In some areas the action of freezing and thawing becomes important in the erosion process. Impermeable ice usually forms in areas of fine textured soils where a supply of moisture is available before the advent of cold weather. Under these conditions the ice often persists throughout the winter and is still present when the spring thaw occurs. In some instances water tends to run over the surface of the ice and not detach soil particles, but it is possible for the ice in a surface layer to thaw during a warm period and create a very erodible situation. Spring rains with ice at shallow depth may wash away the loose material on the surface.

In some areas of the Pacific Southwest, particularly those underlain by marine shale, freezing and thawing alters the texture of soil near the surface, and thus changes the infiltration characteristics. These areas generally do not receive enough snow or have cold enough temperatures to build a snow pack for spring melt. Later in the year soil in a loosened condition is able to absorb a large part of the early rainfall. As rains occur during the summer, the soil becomes compacted on the surface, thus allowing more water to run off and affording a greater chance for erosion.

Topography

Watershed slopes, relief, floodplain development, drainage patterns, orientation and size are basic items to consider in connection with topography. However, their influence is closely associated with geology, soils, and cover.

The Pacific Southwest is made up of land with all classes of ground cover. The high mountain areas generally have the most vegetation, while many areas in the desert regions have practically none. The abundance of vegetation is related in a large degree to precipitation. If vegetative ground cover is destroyed in areas where precipitation is high, abnormally high erosion rates may be experienced.

Differences in vegetative type have a variable effect on erosion and sediment yield, even though percentages of total ground cover may be the same. For instance, in areas of pinyon-juniper forest having the same percentage of ground cover as an area of grass, the absence of understory in some of the pinyon-juniper stands would allow a higher erosion rate than in the area of grass.

Land Use

The use of land has a widely variable impact on sediment yield, depending largely on the susceptibility of the soil and rock to erosion, the amount of stress exerted by climatic factors and the type and intensity of use. Factors other than the latter have been discussed in appropriate places in this guide.

In almost all instances use either removes or reduces the amount of natural vegetative cover which reflects the varied relationships within the environment. Activities which remove all vegetation for parts of each year for several years or permanently are cultivation, urban development and road construction. Grazing, logging, mining, and fires artifically induce permanent or temporary reduction in cover density.

High erosion hazard sites, because of the geology, soils, climate, etc., are also of high hazard from the standpoint of type and intensity of use. For example, any use which reduces cover density on a steep slope with erodible soils and severe climatic conditions will strongly affect sediment yield. The extent of this effect will depend on the area and intensity of use relative to the availability of sediment from other causes. Construction of roads or urban development with numerous cut and fill slopes through a large area of widespread sheet or gully erosion will probably not cause a change in sediment yield classification. Similar construction and continued disturbance in an area of good vegetative response to a favorable climate can raise yield by one or more classifications.

Use of the land has its greatest potential impact on sediment yield where a delicate balance exists under natural conditions. Alluvial valleys of fine, easily dispersed soils from shales and sandstones are highly vulnerable to erosion where intensive grazing and trailing by livestock have occurred. Valley trenching has developed in many of these valleys and provides a large part of the sediment in high yield classes from these areas.

Channel Erosion and Sediment Transport

If a stream is ephemeral, runoff in traversing the dry alluvial bed may be drastically reduced by transmission losses (absorption by channel alluvium). This decrease in the volume of flow results in a decreased potential to move sediment. Sediment may be deposited in the streambed from one or a series of relatively small flows only to be picked up and moved on in a subsequent larger flow. Sediment concentrations, determined from field measurements at consecutive stations, have generally been shown to increase many fold for instances of no tributary inflow. Thus, although water yield per unit area will decrease with increasing drainage area, the sediment yield per unit area may remain nearly constant or may even increase with increasing drainage area.

In instances of convective precipitation in a watershed with perennial flow, the role of transmission losses is not as significant as in watersheds with ephemeral flow, but other channel factors, such as the shape of the channel, may be important.

For frontal storm runoff the flow durations are generally much longer than for convective storms, and runoff is often generated from the entire basin. In such instances, sediment removed from the land surfaces is generally carried out of the area by the runoff. Stream channel degradation and/or aggradation must be considered in such cases, as well as bank scour. Because many of the stream beds in the Pacific Southwest are composed of fine-grained alluvium in well defined channels, the potential for sediment transport is limited only by the amount and duration of runoff. Large volumes of sediment may thus be moved by these frontal storms because of the longer flow durations.

The combination of frontal storms of long duration with high intensity and limited areal-extent convective activity will generally be in the highest class for sediment movement in the channels. Storms of this type generally produce both the high peak flows and the long durations necessary for maximum sediment transport.

Sediment yield may be substantially affected by the degree of channel development in a watershed. This development can be described by the channel cross sections, as well as by geomorphic parameters such as drainage density, channel gradients and width-depth ratio. The effect of these geomorphic parameters is difficult to evaluate primarily because of the scarcity of sediment transport data in the Pacific Southwest.

If the cross section of a stream is such as to keep the flow within defined banks, then the sediment from an upstream point is generally transported to a downstream point without significant losses. Confinement of the flow within alluvial banks can result in a high erosional capability of a flood flow, especially the flows with long return periods. In most channels with wide floodplains, deposition on the floodplain during floods is often significant, and the transport is thus less than that for a within bank flow. The effect of this transport capability can be explained in terms of tractive

CLIMATIC ENVIRONMENTS

PACIFIC SOUTHWEST AREA

Adapted from Climatic Atlas of the United States by Stephen S. Visher.

Use of the Rating Chart of Factors Affecting Sediment Yield in the Pacific Southwest

The following is the sediment yield classification originally presented on page 2.

Classification	Rating	Sediment Yield AF/sq.mi.
1	> 100	3.0
2	75 - 100	1.0 - 3.0
3	50 - 75	0.5 - 1.0
4	25 - 50	0.2 - 0.5
5	0 - 25	< 0.2

In most instances high values for the A through G factors should correspond to high values for the H and/or I factors.

An example of the use of the rating chart is as follows:

A watershed of 15 square miles in western Colorado has the following characteristics and sediment yield levels:

	Factors	Sediment Yield Level	Rating
A	Surface geology	Marine shales	10
B	Soils	Easily dispersed, high shrink-swell characteristics	10
C	Climate	Infrequent convective storms, freeze-thaw occurrence	7
D	Runoff	High peak flows; low volumes	5
E	Topography	Moderate slopes	10
F	Ground cover	Sparse, little or no litter	10
G	Land use	Intensively grazed	10
H	Upland erosion	More than 50% rill and gully erosion	25
I	Channel erosion	Occasionally eroding banks and bed but short flow duration	5
		Total	92

This total rating of 92 would indicate that the sediment yield is in Classification 2. This compares with a sediment yield of 1.96 acre-feet per square mile as the average of a number of measurements in this area.

FACTORS AFFECTING SEDIMENT YIELD IN THE PACIFIC SOUTHWEST

Sediment Yield Levels	A SURFACE GEOLOGY	B SOILS	C CLIMATE	D RUNOFF	E TOPOGRAPHY	F GROUND COVER	G LAND USE	H UPLAND EROSION	I CHANNEL EROSION & SEDIMENT TRANSPORT
High	(10)* a. Marine shales and related mudstones and siltstones.	(10) a. Fine textured; easily dispersed; saline-alkaline; high shrink-swell characteristics. b. COE FEASIBILITY STUDY SEDIMENTATION CURVE

COE Feasibility Study

VII. SEDIMENT YIELD

General

7-01 There is limited sediment yield data in the study area. The information available for Clark County shows no specific trends or is based on studies conducted for other areas which have somewhat different watershed and channel conditions. An average annual sediment yield vs. drainage area relationship developed by B&V based on information from Corps reports, (discussed in their report, ref. 28) was used to determine the average annual yield in acre-feet for each of the proposed detention basins. Estimated average annual sediment delivery rates to detention basins considered in the Las Vegas Wash basin range from 0.3 to 0.8 acre-feet per square mile. Sediment yield rates as a function of drainage area, as developed in Corps of Engineers reports for the Las Vegas and Phoenix areas, are shown on plate 46. The sediment yield rates for the Las Vegas and Henderson detention basins (proposed in 1959, ref. 1) were based on the Trilby Wash Dam rate reported by the Soil Conservation Service. From these points, an upper limit line was drawn to derive a recommended minimum average annual sediment yield for planning and design purposes.

7-02 The values recommended by B&V, were checked against the values that would be determined using the publication, "Factors Affecting Sediment Yield and Measures for the Reduction of Erosion and Sediment Yield," Pacific Southwest Inter-Agency Committee, Oct. 1968 (ref. 34). The average annual sediment yield derived using this report gave values of the range of 0.3 to 0.7 acre-feet per square mile. Therefore, the B&V recommended line seems reasonable and was adopted to determine the sediment yield rates for each of the proposed detention basins. The results are given in table 40.

YANG PAPER

The basis for establishing the event specific yield is the ability of the alluvial fan to transport materials generated in the watershed. The basic assumption is that at the location of the dike, flows down the fan will have reached their equilibrium sediment carrying capacity. The distance between the fan apex and the dike is several miles. Over that reach, particles which cannot be transported will have been deposited or other materials from the fan surface will have been scoured to satisfy the carrying capacity. This computation was necessary for several reasons:

- To estimate the total sediment load by event for use in the average annual yield computation using the integration process.

- To establish a sediment transport versus discharge relationship

- To estimate a particle size distribution of the sediment

The relationship used to simulate sediment transport capacity was one developed by Yang. Several different equations can be used to model stream sediment carrying capacity. The application of a particular equation is typically a function of the hydraulic characteristics of the channel and the characteristics of the sediment being transported. In 1991 C.T. Yang and S. Wan published a study in the ASCE Hydraulics Journal entitled "Comparisons of Selected Bed Material Load Formulas". This paper presented the results of their study which compared several different transport equation for various conditions of channel hydraulics. A review of this publication indicated that for channel conditions similar to the Range Wash Channel (steep

slopes, Froude numbers near one and coarse particles) Yang's formulation provided the most reliable results.

The use of Yang's formulation is not inconsistent with the standard of practice. Yang's methodology has long been acknowledged as an appropriate approach. This is demonstrated by its inclusion as one of the computational options available in HEC-6.

5. Flow concentration can occur on riprap-protected embankments. Flow concentrations of 1.33 to 3.33 were observed.

6. Riprap design criteria for sizing riprap subjected to overtopping flow conditions is presented based on near-prototype test data.

Comparisons of Selected Bed-Material Load Formulas

By Chih Ted Yang,[1] Fellow, ASCE, and Shenggan Wan[2]

Abstract: Comparisons are made of the overall accuracy as well as the accuracy within different ranges of sediment concentration, Froude number, and slope for seven bed material load formulas. Four formulas that can compute bed-material load transport by size fraction are used to determine the particle size distribution of the bed materials in transportation. One thousand, one-hundred-nineteen sets of laboratory data and 319 sets of river data in the sand size range are used to evaluate and compare the accuracy of these formulas. The overall accuracy of formulas in descending order are those of Yang, Engelund and Hansen, Ackers and White (d_{50}), Laursen, Ackers and White (d_{35}), Colby, Einstein, and Toffaleti formulas when applied to laboratory flumes. The accuracy in descending order when applied to natural rivers are the formulas by Yang, Toffaleti, Einstein, Ackers and White (d_{50}), Colby, Laursen, Engelund and Hansen, and Ackers and White (d_{35}). However, these ratings may vary depending on the values of sediment concentration, Froude number, and slope of the data used in the comparison. The study also indicates that Yang's formula by size fraction can accurately predict the size distribution of bed material in transportation, while Einstein's hiding and lifting correction factors overcorrected the effect of nonuniform size distribution of bed material on total bed-material transport.

Introduction

There are numerous sediment transport formulas developed by different investigators for the prediction of bed load, suspended load, and total bed-material load in alluvial channels. Comparisons of the accuracy of these formulas were made by Yang and Stall (1973), White et al. (1975), Yang (1976), Alonso (1980), Brownlie (1981), Yang and Molinas (1982), the ASCE Task Committee ("Relationships between Morphology" 1982), Yang (1988), Vetter (1989), and the German Association for Water Resources and Land Improvement (1990), among others. These comparisons emphasize the overall accuracy of formulas without given detailed information of the hydraulic and sediment conditions under which measurements were made. Depending on the conditions under which data were collected for comparisons, the same formula could have different ratings of accuracy. This often causes confusion in the profession in the selection of formulas for solving engineering problems.

Measured sediment concentration, Froude number, and slope are used as parameters to define the hydraulic and sediment conditions. The analyses in this paper are limited to total bed-material load formulas due to the lack of general criteria to separate bed load from suspended load. Comparisons between computed bed-material size distribution and size distribution of bed materials in bed and in transportation are also made in this paper. The computer programs published by Stevens and Yang (1989) are used herein for

Note. Discussion open until January 1, 1992. To extend the closing date one month, a written request must be filed with the ASCE Manager of Journals. The manuscript for this paper was submitted for review and possible publication on June 14, 1990. This paper is part of the ***Journal of Hydraulic Engineering***, Vol. 117, No. 8, August, 1991. ©ASCE, ISSN 0733-9429/91/0008-0973/$1.00 + $.15 per page. Paper No. 26039.

the comparison of formulas. Data used for comparisons in this paper are limited to sediment transport in the sand size range.

Bed-Material Load Formulas

The selection of formulas for comparison in this paper is based on: (1) The formula's theoretical basis; (2) the extent of testing by the original author and independent investigators; and (3) the extent of use by engineers and researchers. The bed-material load formulas selected for comparison in this paper are those proposed by Einstein (1950), Laursen (1958), Engelund and Hansen (1967), Toffaleti (1968), Colby (1964), Ackers and White (1973), and Yang (1973). Among these formulas, those developed by Einstein, Laursen, Toffaleti, and Yang can be used to compute bed-material load or concentration by size fraction to determine the particle size distribution of the bed materials in transport. The representative sediment diameter for Ackers and White's formula can either be the median particle diameter (d_{50}) or the particle size of which 35% are final (d_{35}). The representative sediment diameter for Yang's formula is d_{50}. It should be pointed out that in addition to his 1973 equation for sand transport, Yang proposed an equation in 1979 for sand transport in which the critical unit stream power required at incipient motion can be neglected (Yang 1979). He also proposed an equation for gravel transport in 1984 (Yang 1984). Due to the range of data available for comparison, only Yang's 1973 formula is selected for comparison in this paper. Detailed descriptions of formulas used in this paper are published by Stevens and Yang (1989).

Accuracy of Formulas

A total of 1,438 sets of laboratory and river data are used in this paper to determine the accuracies of bed-material load formulas. They include 1,119 sets of laboratory data collected by Guy, Simons, and Richardson (1966), Gilbert (1914), Nomicos (1956), Vanoni and Brooks (1957), Kennedy (1961), Stein (1965), Williams (1967), White and Day (1982), and Schneider (unpublished material, 1971). Total bed-material concentrations were measured directly for these laboratory data that eliminate the uncertainty of unmeasured load near the bed surface.

A total of 319 sets of river data were also used in the analyses. These river data were collected from the Niobrara River (Colby and Hembree 1955), the Middle Loup River (Hubbell and Matejka 1959), the Rio Grande River (Nordin 1964), the Mississippi River (Jordan 1965), and Mountain Creek (Einstein 1944). Data judged by their original investigators as of questionable accuracy were excluded from our analyses. To ensure the accuracy of field data, only those sets of data with hydraulic and sediment measurements made within a 24-hr period are used. Total bed-material load was measured from the Niobrara River, the Middle Loup River, and the Mountain Creek. The amount of unmeasured load near the riverbed for the Rio Grande River and the Mississippi River remains to be determined. Table 1 summarizes the hydraulic and sediment data from laboratory flumes and natural rivers analyzed in this paper.

The basic parameter used in this paper for the determination of the accuracy of a formula is the discrepancy ratio, which is defined as

Note: 1 ft = 30.48 cm, and °F = 9/5 °C + 32

$$R = \frac{C_c}{C_m} \qquad (1)$$

where C_c = computed bed-material concentration from a formula in parts per million by weight; and C_m = measured bed-material concentration in parts per million by weight. The mean value $\bar{R}$ and standard deviation σ are defined as

$$\bar{R} = \frac{\sum_{i=1}^{j} R_i}{j} \qquad (2)$$

and

$$\sigma = \sqrt{\frac{\sum_{i=1}^{j} (R_i - \bar{R})^2}{j-1}} \qquad (3)$$

In addition to $\bar{R}$ and σ, the percentages of data that can be found within ±25%, and ±50%, and ±75% of the computed concentrations from a given formula are also computed as additional indications of the accuracy of a formula. Data are regrouped into different ranges of dimensionless parameters, i.e., measured concentration C_m, Froude number F_r, and slope S. It is assumed that energy slope can be replaced by water surface slope without causing much error. The discrepancy ratios associated with each of the given parameters are defined in Table 2. Detailed results of comparisons are shown in Tables 3–8, and the summary of comparison is given in Table 9. Some of these comparisons are plotted on Figs. 1–3.

Based on the summary results shown in Table 9, the Yang (d_{50}) formula

TABLE 2. Definitions of Discrepancy Ratios Based on Different Parameters

Source (1)	C_* (2)	F_* (3)	S (4)

of formulas for river application in descending order are Yang (d_{50}), Toffaleti, Einstein, Ackers and White (d_{50}), Colby, Laursen, Engelund and Hansen, and Ackers and White (d_{35}). The summary river data comparison shows that all eight bed-material load formulas have discrepancy ratios greater than one. This seems reasonable because of the 319 sets of river data used in the comparison, 110 sets did not include bed-material load in the unmeasured zone near the riverbed. The gaging station at the Niobrara River near Cody, Nebraska, is one of the few river stations with total bed-material load measured accurately.

Stevens and Yang (1989) made a comparison between the computed and measured results from the Niobrara River. Their comparison, as shown in Fig. 4, indicates that computed results from the Yang (d_{50}) formula agree with measurements very well. Fig. 4 also shows that the Engelund and Hansen formula overpredicts the total bed-material load while the Laursen, Colby,

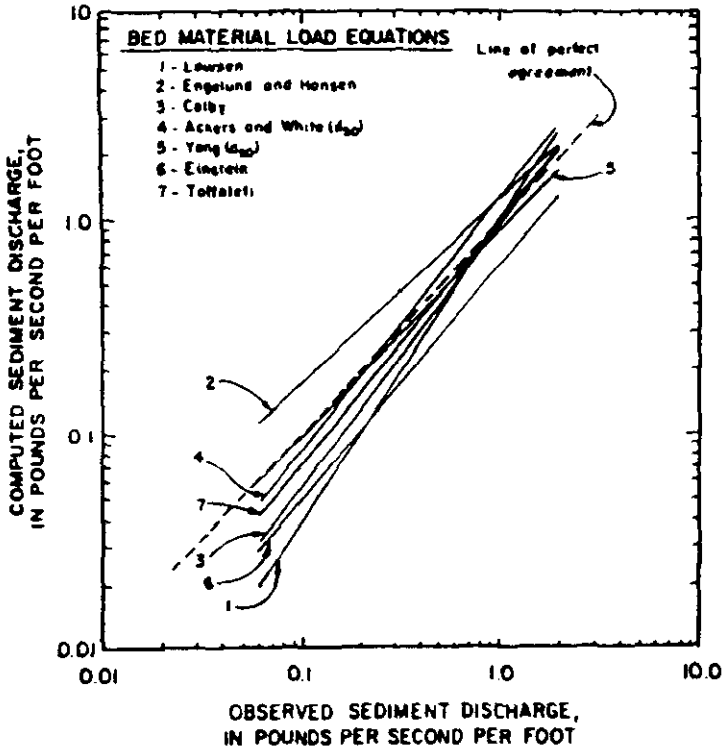

FIG. 4. Comparison of Computed Results by Seven Formulas and Measured Total Bed-Material Discharges from Niobrara River near Cody, Nebraska [from Stevens and Yang (1989)]

Ackers and White (d_{50}), Einstein, and Toffaleti formulas underpredict the total bed-material load in the Niobrara River.

Table 9 shows that different numbers of data sets were used in the comparison of accuracy of formulas. This is caused by the limitations of application of each formula suggested by the original author of the formula. Results in Tables 3–8 indicate that the accuracy of a formula may vary depending on the hydraulic and sediment conditions under which the formula is applied. Engineers may use the information in Tables 3–8 as a reference for selecting formulas to solve engineering problems under different hydraulic and sediment conditions.

Nonuniform Sediment Transport

Our knowledge of particle size distribution of bed materials in transportation is important to the study of reservoir sedimentation distribution and river engineering. Many practicing engineers assume that the particle size distribution of bed materials in transportation is the same as that on the alluvial bed. However, the fact that the average bed-material size decreases in the downstream direction suggests that the average size of bed materials in transportation should be finer than that on the bed. Four bed-material load

Toffaleti	0.58	27	65	87	0.26	305

formulas that can compute transport rate by size fraction are used in this paper to assess the impact of sorting on bed-material size distribution. They are the formulas by Laursen, Yang (fraction), Einstein, and Toffaleti. The Yang fraction formula is identical to his original formula except that the computation is made by size fraction, i.e.

$$C_c = \sum_{i=1}^{j} p_i C_i \quad \ldots \quad (4)$$

where C_i = computed sediment concentration in parts per million by weight in size fraction i; j = total number of size fraction used in the computation; and p_i = percentage of material in size i.

Let us define the discrepancy ratio γ_i as the ratio between median particle size d_c in transportation computed by a formula and actually measured me-

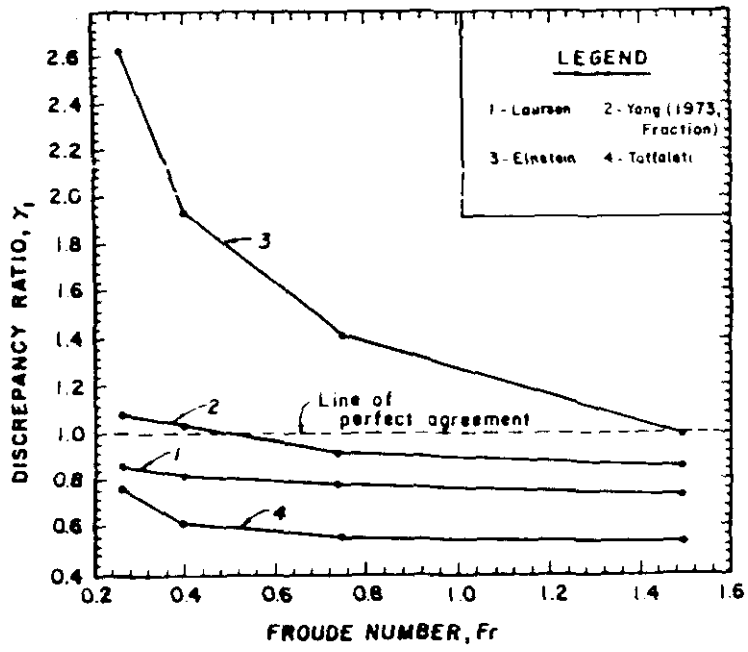

FIG. 5. Comparison between Computed and Measured Particle Size of Bed Material in Transportation

dian particle size d_m in transportation, i.e.

$$\gamma_1 = \frac{d_c}{d_m} \quad \ldots\ldots (5)$$

Let us also define the discrepancy ratio γ_2 as the ratio between the median particle size d_c in transportation computed by a formula and d_{50} of the original bed materials on the alluvial bed, i.e.

$$\gamma_2 = \frac{d_c}{d_{50}} \quad \ldots\ldots (6)$$

γ_1 should give us an indication of the average accuracy of a formula in predicting the size distribution of bed materials in transportation. γ_2 should give us an indication of the reasonableness of a formula in describing the sorting process or the reduction of average particle size in the transport process. The 305 sets of data published by Guy et al. (1966) include size distributions of bed materials on the bed and bed materials in transportation. The results shown in Table 10 indicate that Yang's 1973 fraction formula has the best overall discrepancy ratio of 0.95. The results shown in Table 10 and Fig. 5 also show that the γ_1 value of Yang's 1973 fraction formula is not very sensitive to the variation of Froude number. These results suggest that Yang's 1973 fraction equation can be used with accuracy to predict size distribution of bed materials in transportation. This study also indicates that

the median sizes of bed materials in transportation predicted by Laursen (1958) and Toffaleti (1968) are too small, while those predicted by Einstein (1950) are too large.

Table 11 and Fig. 6 show that, with the exception of the Einstein formula, bed materials in transportation computed by Laursen (1958), Yang (1973) (fraction), and Toffaleti (1968) are finer than the original bed materials on the bed, which is consistent with the sorting phenomena. This sorting process explains why bed-material size should decrease in the downstream direction. The measured γ_2 value of the data published by Guy et al. (1966)

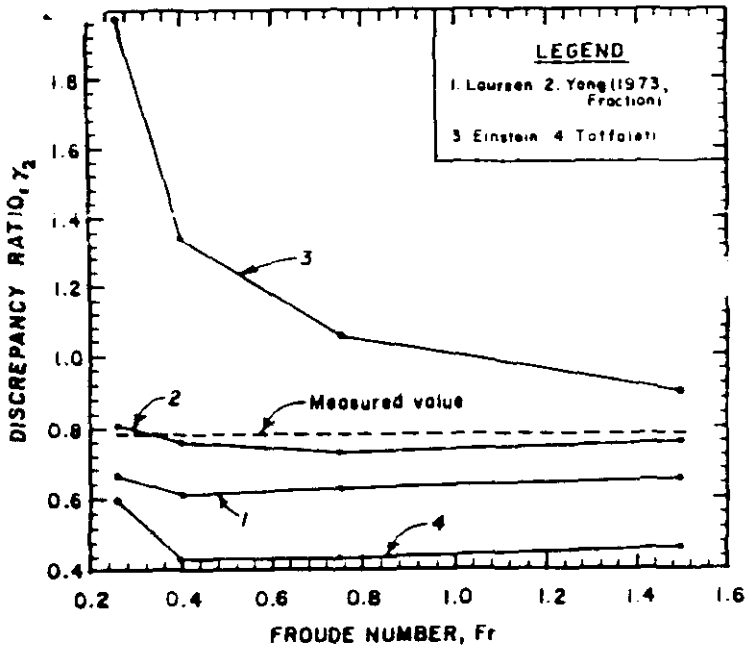

FIG. 6. Comparison between Computed Bed-Material Size in Transportation and Original Bed-Material Size

shows very little variation with changing F_r, and an average value of 0.77 is used in Table 11 for all data. This value is very close to the average value of 0.75 computed by Yang's 1973 fraction equation. Table 11 also shows that the γ_2 value for Yang's fraction equation is not sensitive to the variation of F_r, which is consistent with measurements made by Guy et al. (1966). The γ_2 values of the Einstein (1950) formula are greater than one for all flow conditions, which means the materials in transportation computed by the Einstein formula are coarser than the original bed materials, and the bed-material size would increase in the downstream direction. This unreasonable result may stem from the use of the hiding and lifting correction factors by Einstein.

The total bed-material load computed by the Einstein formula is directly related to bedload. In order to reflect the influence of nonuniform bed-material size distribution and lift force, Einstein introduced the hiding factor ξ and lifting factor Y. The values of ξ and Y vary from 1 to 100 and from 0.25 to 0.85, respectively. The combined effect of ξY on a finer particle could be as high as 340 times the effect on a larger particle when the finer particle is hiding behind the larger one. This effect is especially pronounced when the Froude number is small. This is why the values of γ_1 and γ_2 for the Einstein formula in Tables 10 and 11 decrease with increasing F_r values. *Our study suggests that Einstein's hiding and lifting factors overcorrected the effect of nonuniformity of bed-material size on the transport of graded bed materials.*

Summary and Conclusions

Laboratory and river data are used to compare the accuracy of total bed material load equations. These data are regrouped in accordance with the values of measured bed-material concentration, Froude number, and slope. The effect of nonuniformity of bed-material size on the materials being transported is also studied. These studies reached the following conclusions:

1. Based on 1,119 sets of laboratory data, the overall accuracy of bed material load formulas in descending order are those by Yang (d_{50}), Engelund and Hansen, Ackers and White (d_{50}), Laursen, Ackers and White (d_{35}), Colby, Einstein, and Toffaleti. Formulas developed by Colby, Einstein, and Toffaleti may not be suitable for laboratory flume and small river application. Based on the analyses of 319 sets of river data, the overall accuracy of formula in descending order are those by Yang (d_{50}), Toffaleti, Einstein, Ackers and White (d_{50}), Colby, Laursen, Engelund and Hansen, and Ackers and White (d_{35}).

2. Higher overall accuracy rating of a formula does not guarantee that the formula is superior to others under all flow and sediment conditions. The accuracy rating of a formula may vary depending on the measured values of concentration, Froude number, and slope. Engineers may use the information in Tables 3–8 as a reference for selecting formulas to solve engineering problems under different flow and sediment conditions.

3. Based on the data used in the analyses, Yang's sand transport equation by size fraction can accurately predict the size distribution of bed materials in transportation. The Einstein hiding and lifting correction factors overcorrected the effect of nonuniform size distribution of bed materials on total bed-material transport, especially for flows with low Froude number.

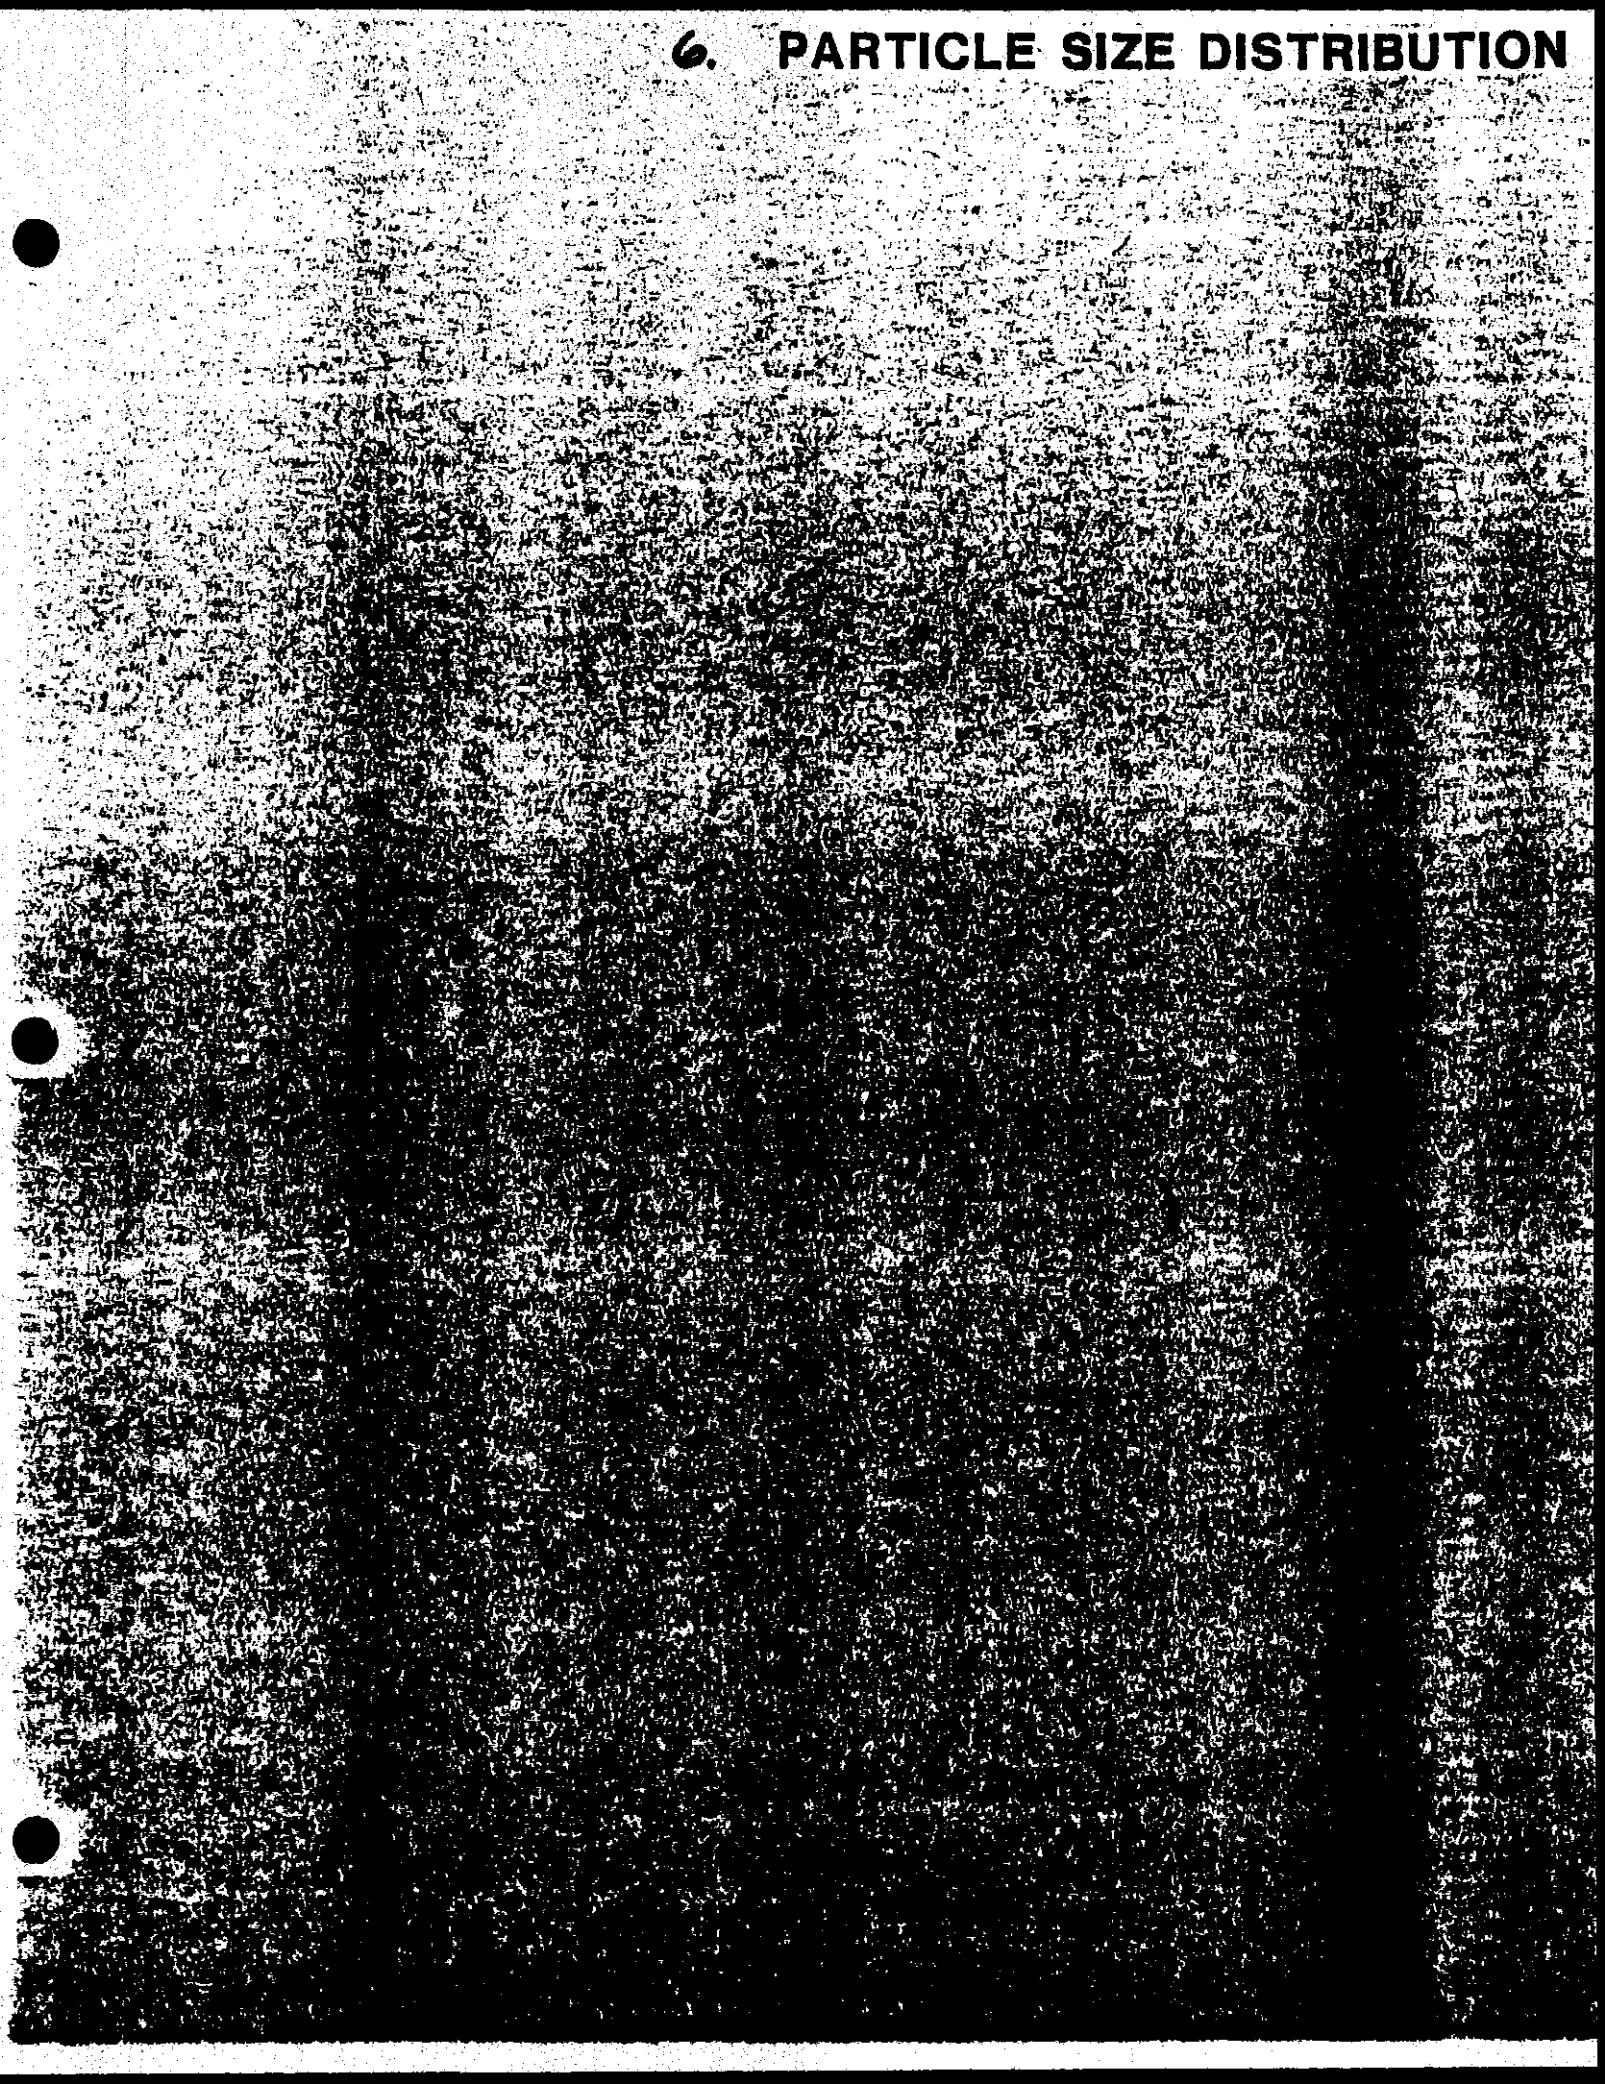
Appendix II. Notation

The following symbols are used in this paper:

C_t, C_m = computed and measured sediment concentration in parts per million by weight, respectively;
C_i = computed sediment cementation in parts per million by weight in size fraction i;
d_t, d_m = computed and measured median bed-material diameters in transportation, respectively;
d_{35}, d_{50} = sediment diameter of which 35% and 50% are finer, respectively;
F_r = Froude number;
p_i = percentage of bed material available in size fraction i;
R = discrepancy ratio between computed and measured values;
$\bar{R}$ = mean value of R;
S = energy or water-surface slope;
Y = Einstein's lifting correction factor;
γ_1, γ_2 = ratio of d_i/d_m and d_i/d_{50}, respectively;
ξ = Einstein's hiding correction factor; and
σ = standard deviation of R.

6. PARTICLE SIZE DISTRIBUTION



PARTICLE SIZE DISTRIBUTION

A key input required into any sediment transport analysis is particle size distribution of the sediment inflow and particle size distribution of the bed materials. In a riverine environment, the assumption is frequently made that the bed material particle size distribution represents the distribution of sediment in the streamflow. On an alluvial fan this assumption is not valid. The alluvial fan is formed because the materials developed at the source cannot be transported down the surface of the fan and therefore materials are deposited which create the characteristic cone appearance of an alluvial fan surface. For this reason, the particle size distribution of materials on the alluvial fan surface generally represent only the larger size fractions. Finer materials are transported down the surface of the fan and are eventually deposited at some downstream point or in a downstream receiving water. This is true on the Range Wash fan.

Several sediment samples were taken on the alluvial fan surface and along the proposed dike alignment. These are included for review. As can be seen from the summary of the samples presented, the particle sizes are heavily skewed toward the larger size fraction with less than 7 percent of the particles having a diameter less than .0625 millimeters. A review of the source materials in the Range Wash basin indicates that there is a significant source of finer size particles. The conclusion reached after reviewing these two conflicting pieces of information is that, as expected on an alluvial fan, the finer materials are being passed across the surface of the fan and are being deposited further downstream in the system.

To confirm that assumption, the SCS Soil Survey for the Las Vegas Valley was reviewed to determine the percentage of fines in the lower portion of the Las Vegas Valley. The attached maps show the downstream portions of the Range Wash basin near its confluence with Las Vegas Wash.

The predominant soils type at the confluence of Range Wash with Las Vegas Wash is Glencarb. The designation on the attached maps are map symbol 200, 206, and 222. As the engineering index properties table demonstrates, these materials have a percentage of 70 to 95 percent passing the number 200 sieve. This substantiates the assumption that a significant amount of fine materials are being introduced into the system and are being transported across the alluvial fan and deposited farther downstream.

The precise distribution of the fine and coarse particles cannot be determined directly from this information because the relative volume is unknown. Those samples taken on the fan are skewed toward the coarser particle sizes and those in the valley floor are skewed toward the finer particle sizes. The computation of equilibrium transport and the integration of the various event specific transports helps to define the particle size distribution. As will be discussed in slightly more detail later on, the transport capacity of the alluvial fan flows are sensitive to the relative distribution of fine and coarse particles. This was a significant calibration parameter in determining the event specific transport capacity necessary to match the average annual sediment yield identified in the PSI methodology. The range of values which might be reasonable for fine materials ranges from a minimum of 10 percent to a maximum of 90 percent of the total volume.

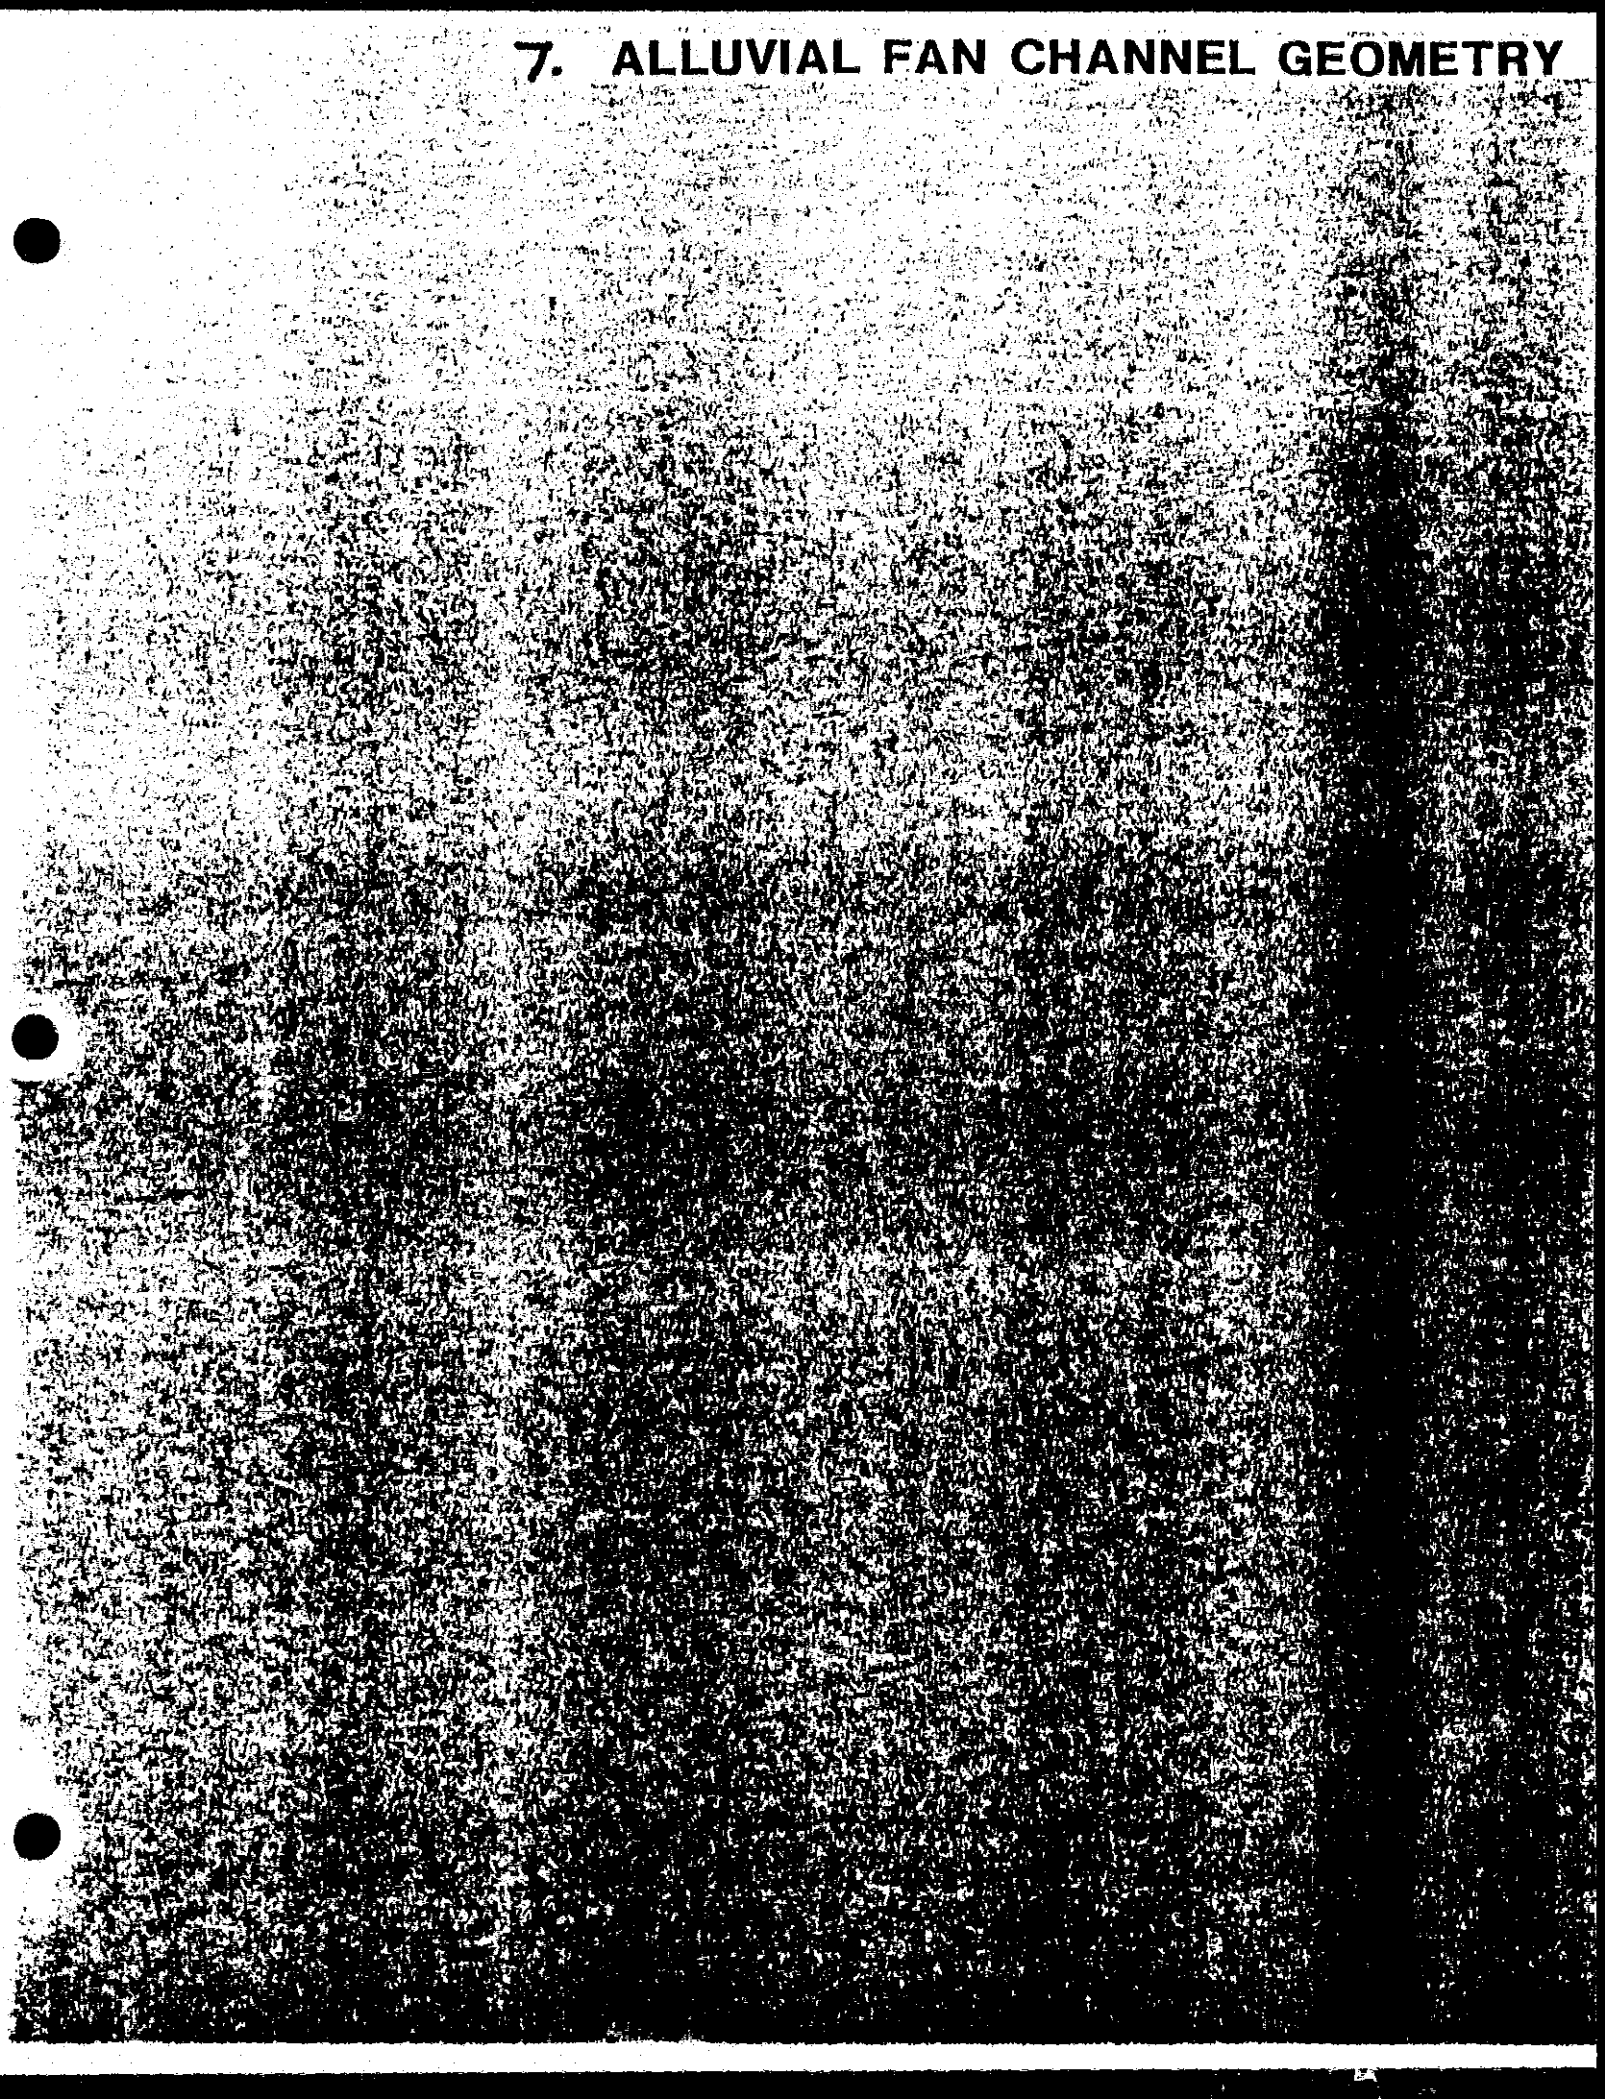
7. ALLUVIAL FAN CHANNEL GEOMETRY



ALLUVIAL FAN CHANNEL GEOMETRY

The geometry of the channel as it flows down the alluvial fan is a key component in establishing transport capacity. The nature of alluvial fan flooding is indeterminate and makes the definition of channel geometry very difficult. We have used the Dawdy/FEMA equation to estimate the top width of an alluvial fan channel. The relationship identifies top width as a function solely of discharge. Dawdy and FEMA developed this relationship and have demonstrated its applicability to single channel reaches on alluvial fans.

We have evaluated the potential for reaching a multiple channel condition on the Range Wash alluvial fans. Based on the absence of physical evidence identifying a single channel and previously published FEMA references which relate length of the single channel and the ratio of canyon slope to fan slope, we have determined that multiple channels are likely down the alluvial fan. The hydraulic characteristics of FEMA multiple channels result in less sediment transport capacity; and therefore, from the viewpoint of sizing the dike, a less conservative condition than single channel flow. However, for the purposes of this analysis, we have assumed that flows are conveyed from the apex of the fans to the dike in a single FEMA channel. This results in the most conservative design condition; and therefore, provides the highest degree of confidence in the design of the dike.

BOYLE ENGINEERING CORPORATION

Project PANTEX WASH
Job No. [illegible]
By [illegible] Date 1/23/92

Description [illegible]

SHEET 1/1

DAWOY'S EQUATION

$T_s = 9.5 Q^{0.4}$ where T_s = Top width of single channel flow (feet)

Q = discharge (cfs)

$T_s = 9.5 (7030)^{0.4}$

$T_s \doteq 330$ feet (at Peak Discharge)

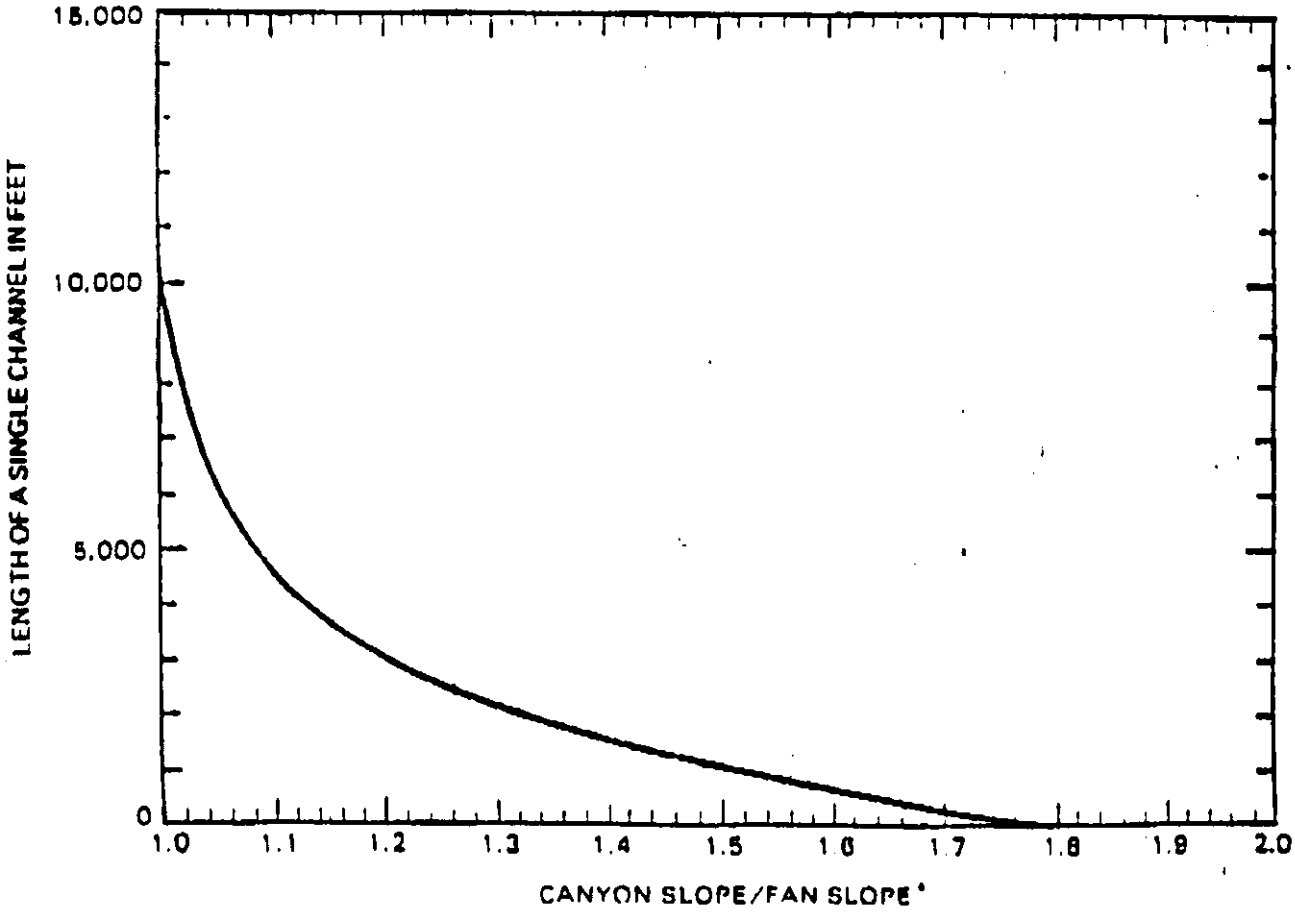
$T_m = 3.8\ T_s$ where T_m = Aggregate width of multiple channel flow (feet)

$T_m = 3.8 (330)$

$T_m = 1254$ feet

ACCORDING TO FIGURE A5-1, THE MAXIMUM LENGTH OF A SINGLE CHANNEL IS LESS THAN 15,000 FEET. THE APPROXIMATE DISTANCE FROM THE APEX OF THE FAN TO OUR DESIGN POINT IS APPROXIMATELY FOUR MILES. AS A CONSERVATIVE APPROACH, WE ARE USING THE SINGLE CHANNEL WIDTH.

FIGURE A5-1
RELATIONSHIP BETWEEN LENGTH OF A SINGLE CHANNEL
AND RATIO OF CANYON SLOPE TO FAN SLOPE



* Canyon slope should normally be computed along the stream bed of the lower canyon to a point upstream of the canyon mouth where there is a notable change to a steeper gradient. Fan slope should normally be computed for the upper portion of the fan to a point downstream of the fan apex where there is a notable change to a flatter gradient.

8. FAN EQUILIBRIUM

FAN EQUILIBRIUM

The sizing of the diversion dike is very sensitive to the inflow sediment volume during the 100-year event. As discussed in previous sections, no data exists to directly estimate the 100-year sediment inflow volume (or particle size distribution). Consequently, Boyle chose to estimate the equilibrium sediment transport down the fluvial fan for several events and integrate these values to compute an average annual sediment yield. Estimates of average annual yield have been made for the Las Vegas Valley by the Corps and have been previously developed for Range Wash by Boyle based on the Corps estimates and PSI.

The foundation for the analysis is to establish an event specific equilibrium transport down the alluvial fan which yields an average annual sediment yield as determined from the previous PSI analysis. Then sediment and flood discharges from the 100-year event are routed down the alluvial fan and along the dike to establish differences in sediment transport capacity and, thus, compute the required dike height.

Because of a lack of actual data defining the inflow sediment, various assumptions were made regarding sediment flows down the fan. These assumptions included:

- Inflow particle size distribution
- Roughness coefficient
- Temperature
- Sediment rating curve
- Total inflow sediment volume.

The assumed inflow particle size distribution has been discussed previously. The specific relationship of fine materials to coarse materials was difficult to ascertain from sediment records taken on the fan or those taken on the valley floor. The assumption was made that, at equilibrium, variations in the initial particle size distribution would be insignificant. This was confirmed through calibration and sensitivity runs which adjusted the coarse material size distribution without significant changes in equilibrium sediment transport.

The amount of fine particles in the inflow did have a significant influence on the total equilibrium sediment volume. Because fine materials are not subject to the mathematical relationships established for coarse particles, HEC-6 assumes that these are transported through the system without deposition. Given the velocity and character of flows down the fan this is a reasonable assumption. The concentration of fine particles does affect the viscosity of the water and therefore affects transport capacity. This was determined to be a significant calibration variable. The relationship of fine particles to coarse particles was adjusted until the integration of the event specific yields matched the average annual yield. A final particle distribution of 30 percent fine particles (materials less than .0624 millimeters) and 70 percent of coarse materials resulted in an acceptable correlation. This value is also within the bounds of reasonable estimates established by a review of fan surface particle sizes and valley floor soil surveys.

The roughness coefficient used in the sediment transport analysis is a function of bed material particle size and bed form. According to Design Guidelines and Criteria for Channels and Hydraulic Structures on Sandy Soils, a 1981 Simons and Li publication, bed form comprises the most significant component of roughness and is the determining factor for an "n" value in a sediment transport analysis. To establish an "n" value, the bed form must be determined. Stream power is a determining factor to establish bed forms. Based on a stream power equation which combines sheer stress and velocity, a stream power of 10.5 was identified. This stream power indicates that the bed form is in the antidune or plane bed range with an "n" value

of between .02 and .025. For this analysis an "n" value of .022 was assumed. Computations supporting this estimate are included in the "Roughness" section.

Temperature also plays a role in sediment transport capacity. The dynamics of rainfall and runoff in the Las Vegas Valley indicate that storm water is generally going to be of relatively high temperature. Most rainfall events occur as thunderstorms during relatively warm spring and summer days. Ground temperatures may be 100 degrees or more. The diversion dike is located relatively far downstream in the watershed and intercepts water after it has had a chance to pass over large expanses of land surface. Gages measuring temperature are limited. One gage station, Las Vegas Wash near Henderson, has recorded temperature. A review of this gage indicates that water temperatures approaching 80 degrees Fahrenheit are possible. Because this gage is located slightly lower in the watershed than the dike, a water temperature of 70 degrees was assumed. The referenced gage information is presented in the "Temperature" section.

A rating curve of sediment inflow versus discharge is required as part of the HEC-6 input. This curve requires an estimate of the total inflow volume and an estimate of the particle size distribution of the inflowing sediments. As previously discussed, a distribution of 30/70 for fines/coarse materials was determined. This was an iterative approach and is described in more detail in the average annual yield calibration discussion. To establish an estimate of total sediment inflow volume a review of similar studies was performed. Boyle collected several studies and evaluated the relationship between average annual yield and event specific yield. As previously mentioned, it was not felt that these were sufficiently compelling to use as the basis for the relationship between average annual yield and event specific yield. However, it was felt that this would provide a sufficient basis for the initial estimate. A ratio of seven between the 100-year event and the average annual event was used as a inflow sediment

estimate. A summary of the findings of the literature review, as well as pertinent sections of the literature are included in the "Inflow Volume" section.

The actual equilibrium transport capacity down the fan is a function of geometry and hydraulic characteristics rather than the inflow characteristics. Those materials which cannot be transported will be deposited and those material size fractions having a greater transport capacity will be scoured from the bed. The model runs indicate that equilibrium is achieved very soon after flows reach the alluvial fan and that the relative size and total volume of materials transported is relatively constant down the fan.

To establish the sediment rating curve as a function of discharge, literature was reviewed and a power function was identified. The exponent for this relationship varied from 1.07 to 1.84. A value of 1.5 was used as representing the overall average. References are included in the "Q vs Sed" section.. The relationship

$$q_{sed} = k*Q^{1.5}$$

where:

q_{sed} = sediment load in cubic feet per second

k = conversion constant and

Q = Discharge in cubic feet per second

The k coefficient was determined by integrating all discharges to the 1.5 power and dividing that value into the total sediment volume of seven times the average annual sediment volume. A rating curve was then established which related sediment load to clear water discharge.

This information established the foundation for the HEC-6 analysis. While this analysis is founded on several assumptions regarding the inflow sediment characteristics the application is relatively straightforward and lends itself to analysis using HEC-6. The analysis performed is

essentially a one-dimensional sediment transport analysis. The input information developed above resulted in a final run which was used for all subsequent analyses.

As previously described, the determination of the characteristics of alluvial fan flows, water and sediment, at equilibrium was critical to all subsequent analyses.

Sensitivity runs were made to test the effects of various temperature, roughness, inflow volumes and particle size distributions. Representative outputs are included in this notebook under the "Sensitivity Analyses" section. These demonstrate the relative insensitivity of temperature, roughness and inflow volume on the equilibrium transport.

The particle size distribution proved to be a very sensitive input parameter. This variable was used as the primary calibration tool to assure that the integrated event specific yields equalled the average annual yield predicted by PSIA. This process involved assuming a distribution of the fines relative to coarse particles and running the simulation model. If the integration did not result in an acceptable agreement with PSIA the distribution was changed. The final distribution of 30/70 was arrived at in this method and was verified using the previously discussed soil surveys.

Subsequent steps used in the analysis begin to diverge from the intended application of HEC-6. Several additional assumptions were required to simulate alluvial fan processes using HEC-6. HEC-6 is essentially a one-dimensional steady state sediment transport model. That is, it is intended to simulate riverine sediment transport through a fixed channel section with a movable bottom. The alluvial fan discharges are generally characterized by a very steep hydrograph with significant changes in discharge versus time. The width of the channel is also variable as a function of discharge, as determined by Dawdy/FEMA's approach. These two limitations

required a slight adaptation to the application of HEC-6 which will be described in subsequent sections.

Another limitation of HEC-6 is that changes in channel invert elevation and slope due to scour result in an instantaneous change in the sediment transport carrying capacity. While the instantaneous change in sediment carrying capacity is indeed consistent with the physical phenomenon being simulated, the impacts of that change are felt over a longer channel reach than the model predicts. This resulted in an overestimation of the impact at a particular cross section, but the results were indicative of total deposition or total scour through the system. Subsequent sections will address how those anomalies were addressed in our analysis.

ROUGHNESS

BOYLE ENGINEERING CORPORATION

Project: SALINE WASH
Job No.: QN 100 300 10
By: TSC Date: 10/28/91
Description: ESTIMATE ROUGHNESS
SHEET 1/1

FROM "DRAINAGE AND FLOOD CONTROL DESIGN GUIDELINES AND CRITERIA" SIMONS, LI, AND ASSOCIATES (1981)

IN ORDER TO ESTIMATE A MANNING'S "n" VALUE FOR THE ALLUVIAL STREAM, IT IS NECESSARY TO TAKE THE BED FORM ROUGHNESS INTO CONSIDERATION. THE TYPE OF BED ROUGHNESS IS RELATED TO STREAM POWER, ACCORDING TO FIGURE 2-8.

$$\text{STREAM POWER} = \tau_0 V \quad \left(\frac{\text{ft-lb}}{\text{ft}^2\,\text{sec}}\right)$$

AND, $\tau_0 = \frac{1}{8} \rho f_0 V^2$

where: $\rho = 1.94 \frac{\text{lb-sec}^2}{\text{ft}^4}$

$f_0 = 0.066$ (SIMONS, ET AL)

V = velocity of flow (ft/s) (assume velocity @ critical depth for 100 YR FLOW)

$\tau_0 = \frac{1}{8} (1.94)(0.066)(8.7)^2$

$\tau_0 = 1.21$

SO, STREAM POWER = $(1.21)(8.7) \doteq \underline{10.5}$

FROM FIGURE 2-8, THE BED FORM IS ANTIDUNES OR FLAT BED

FROM TABLE 2-2, $n = .025$ FOR ANTIDUNES
$n = .020$ FOR PLANE BED

∴ WE WILL ASSUME $\underline{n = .022}$

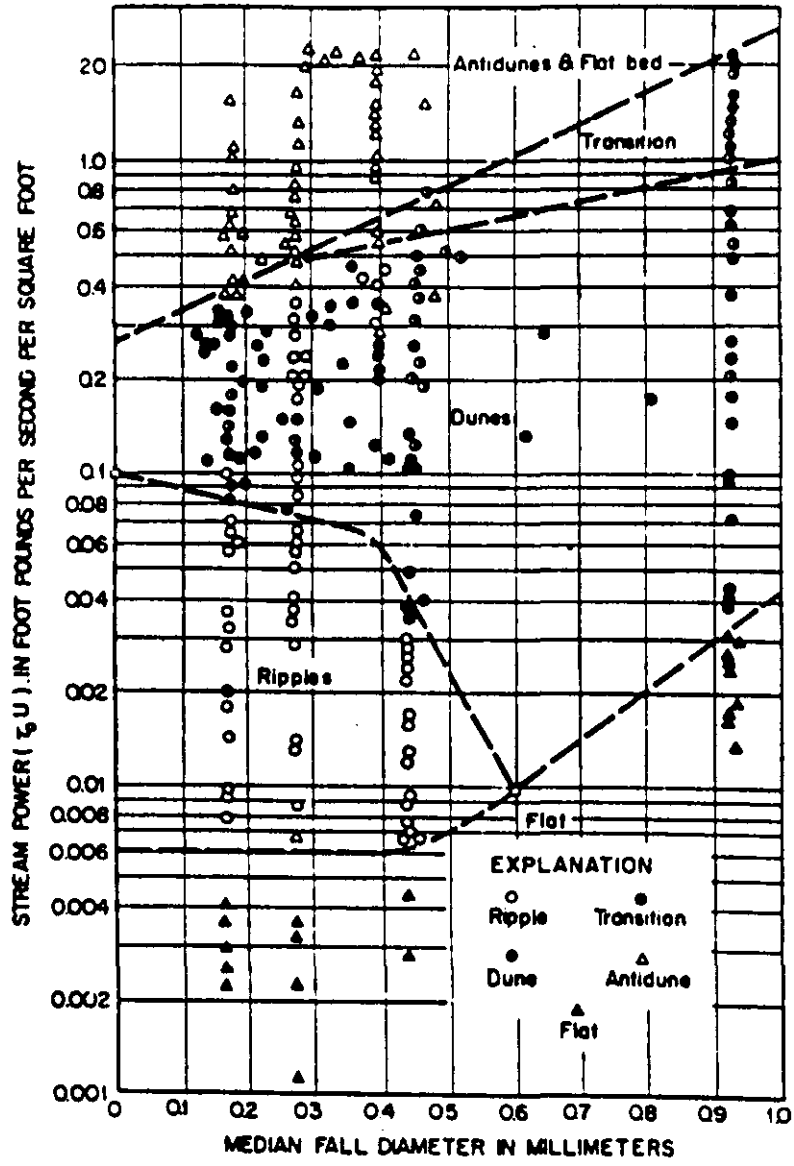


Figure 2-8. Relation of bed forms to stream power and median fall diameter of bed sediment (after Simons and Richardson, 1966).

3. In an ASCE technical paper (Reference 15) by Mr. Kenneth Renard, Southwest Rangeland Watershed Research Center, Tucson, Arizona, a comparison was made of several sediment yield equations or techniques. The methods were applied to the Walnut Gulch Experimental Watershed, a 58-square mile drainage area in southeastern Arizona operated by the Science and Education Administration of the United States Department of Agriculture. The watershed subareas varied in size from 0.136 square miles to 1.32 square miles and the record length averaged 14 years. The average annual measured sediment accumulation varied from 0.09 to 0.51 acre-feet/square mile/year for nine subareas within the study area. The PSIAC equation applied to these same watersheds resulted in average annual sediment yields ranging from 0.16 to 0.38 acre-feet/square mile/year.

The above comparisons on sediment yield methods and production rates would indicate that the PSIAC equation used for the Bullhead City study would generate reasonable values of average annual sediment yield for a reconnaissance level study.

In order to size the proposed desilting basins for a recurrence interval lower than the annual storm event (≃ 2.2 years), it was necessary to find a procedure to provide sediment yield for an individual storm event. In "Erosion and Sediment Yield" (Reference 14), it was stated that sediment yield was proportioned to runoff. The report presented a summary of sediment yield for the 2-, 10-, 50-, and 100-year recurrence interval storms. A relationship of sediment yields to recurrence interval was noted from the summary. The 100-, 50-, 25-, and 10-year storm sediment yields had approximately a 7:1, 6:1, 4:1, and 3:1 relation to the 2-year sediment yield, respectively.

The above relationship of sediment yield to 2-year storm or the average annual storm (2.2 year ±) was found in Reference 16, where sediment yield was computed for several storm events. The above relationship was also noted when the Modified Universal Soil Loss Equation (MUSLE) was applied to watersheds in the Bullhead City study area.

In conclusion, the above relationships were considered a reasonable relationship of individual storm yields to the average annual sediment yield. Therefore, the approximate sediment yields from the 100-, 50-, 25-, and 10-year storm events for this study were obtained by multiplying the annual sediment yield from the PSIAC equation by 7, 6, 4, or 3, respectively.

6.0 Sediment Yield Estimation

The detailed results of the sediment transport analyses of Cave Creek and Cudia City Wash are presented in this section.

6.1 Cave Creek

Design Storm. The sediment transport model HEC-6 as developed and calibrated in the previous section was applied to estimate sediment yield for the design storm (100-year). The HEC-6 results were then combined with the wash load estimates for upland areas to estimate the total sediment yield. Table 6-1 presents sediment yield, for each particle size, as a result of the design storm.

Average Annual. In section 5.2, sediment yield from 1970 to 1980 was estimated for comparison with sediment removal data. The average annual sediment production during this period was 95,000 tons, or 57 acre-feet. However, gaging station records available for Cave Creek since 1958 indicate that this 11-year period was considerably wetter than the previous 12 years (1958-1969). Average annual runoff volumes were 4,270 acre-feet for 1970 to 1980 and 3,120 acre-feet for 1958 to 1980.

In the inflow report by SLA (1982), a nearly linear correlation between annual water yield and sediment yield was shown with an exponent of 1.07. This relationship was applied to estimate the long-term annual sediment yield based on the period 1958 to 1980, as follows:

$$Qs_{58-80} = \left(\frac{Q_{58-80}}{Q_{70-80}}\right)^{1.07} Qs_{70-80}$$

$$Q_s = 6.96 \times 10^{-5} H_y^{0.261} V^{4.085} TW \quad \text{(Zapato-Chino Creek)} \quad (6d)$$

where

Q_s is the sediment transport capacity (cfs)
V is the average flow velocity (ft/sec)
H_y is the hydraulic depth (ft)
T_W is the top width

The average annual bed-material transport capacity for Los Gatos Creek near the SPRR is determined by using Equation 6a in combination with the average hydraulics of Los Gatos Creek summarized in Table 3.1. The sediment transport capacity for various flood peaks is computed and a regression between the water discharge and bed-material discharge results in the following sediment rating curve

$$Q_s = 1.48 \times 10^{-5} Q^{1.84} \quad (7)$$

where

Q_s is the bed-material transport capacity (cfs)
Q is the water discharge (cfs)

Equation 7 is then used with the daily flow records of Los Gatos Creek at Nunez, which are modified by a weighting factor K (see Equation 2), to determine the bed-material transport rate from 1968 to 1980 of Los Gatos near the SPRR. The resultant average annual bed-material yield between 1968 and 1980 is 207.8 acre-feet.

The bed-material sediment rating curves for Warthan, Jacalitos and Zapato-Chino Creeks were developed in a similar fashion to those for Los Gatos Creek. The resulting sediment rating curves for the three creeks are:

$$Q_s = 7.58 \times 10^{-6} Q^{1.67} \quad \text{(Warthan Creek)} \quad (8a)$$

$$Q_s = 2.01 \times 10^{-5} Q^{1.74} \quad \text{(Jacalitos Creek)} \quad (8b)$$

$$Q_s = 9.94 \times 10^{-5} Q^{1.66} \quad \text{(Zapato-Chino Creek)} \quad (8c)$$

estimated for each basin the Arroyo Pasajero watershed range from .7 percent to 45 percent. The slope length-gradient factor (LS) is determined using the following equation:

$$LS = (\lambda / 72.6)^m (0.065 + 4.56s + 65.41 s^2) \quad (2)$$

Where:

LS = slope length-gradient factor;

m = coefficient related to watershed slope;

λ = slope-length factor;

s = slope-gradient factor equal to the sin of the slope angle in degrees.

The cover index factor (C) represents the relative soil loss reduction due to the influence of ground cover by vegetation, mulch or crop residual, and canopy cover by tall trees or brush. The value of C is unity for clean-tilled, continuous fallow cropland and unprotected construction areas. The average values within the Arroyo Pasajero watershed are estimated to range from about .042 to .649. The values vary considerably depending on vegetation types, cover and land use.

The practice factor (P) describes the reduction in runoff intensity caused by introducing erosion reduction practices on agricultural lands within the watershed. For natural conditions and up-and-down-slope cultivated agricultural areas, P is unity. The rainfall energy factor (R) quantifies the raindrop impact effect and a relative rate of runoff.

Equation (1) estimates average annual erosion rates. It does not estimate sediment delivered to the stream system. Eroded soil materials often move only short distances before a decrease in runoff velocities causes their deposition. They may remain in the fields where they originated or may be deposited on less steep slopes that are remote from the stream system. A conventional method to determine sediment yield (sediment actually reaching the stream system) is to use the concept of sediment delivery ratio. The sediment delivery ratio is the ratio of the actual amount of sediment delivered at a given location to the gross erosion from the drainage area above that location. A modified version of the USLE, which was used in this study, eliminates the need for a sediment delivery ratio by using a runoff factor in lieu of the rainfall energy factor in the USLE. This modification enables prediction of sediment yield resulting from individual storms which can then be used to establish a long-term average value.

The modified universal soil loss equation (MUSLE) begins with the basic assumption that sediment discharge can be related to water discharge by an equation in the form of:

$$q_s = a\, q^b \quad (3)$$

Where:

q_s = instantaneous sediment discharge in tons/day;

q = instantaneous water discharge in cfs;

a = constant

b = constant

The total sediment discharge for a given hydrograph can then be estimated by integrating the above equation over the entire hydrograph as follows:

$$Q_s = \int_0^T a\, q^b\, dt \qquad (4)$$

Where:

Q_s = the total sediment load during the hydrograph in tons;

T = the base of the hydrograph in days;

a and b = the same coefficients as defined in Equation (3).

The above equation may be approximated by:

$$Q_s = \frac{a}{2}\,\frac{2}{b+1}^{n}\, Q\, q_p^{b-1} \qquad (5)$$

Where:

Q = runoff volume in acre-feet;

q_p = peak discharge in cfs;

a and b = the same coefficients as defined in Equation (3).

Equation (5) may be rewritten as

$$Q_s = C\, Q\, q_p^{\beta} \qquad (6)$$

Where:

$C = \frac{a}{2}\,\frac{2}{b+1}^{n}$;

$\beta = b - 1$.

In general, the β term does not appreciably change within the watershed. On the other hand, the coefficient C varies appreciably, depending upon the watershed conditions. The coefficient C, instead of relating to the undefined coefficients a, b and n, may be related to the parameters involved in the USLE as follows:

$$C = KLSCP \tag{7}$$

$$Q_s = \alpha (Q q_p^{\beta}) KLSCP \tag{8}$$

This modified version of the USLE (MUSLE) is used to estimate sediment delivered to the stream. The above form of the equation is one of the two forms proposed by Williams and is considered to be appropriate for the study area.

Determination of the coefficients, α and β, in Equation (8) is based on calibration against total sediment deposits measured within the impoundment basin. They were determined to be 2.74 and 1.5, respectively.

The other parameters were evaluated for each land use within each drainage basin as described in the next section.

6.3.3 Estimation of Watershed USLE Parameters

As previously discussed, the sediment yield from a watershed is based on physical characteristics of the watershed as well as the total volume and peak flow of runoff. The MUSLE approach, adopted for this study, requires the determination of USLE parameters to develop the sediment yield of the watershed. These values were determined using available topographic information, previously published reports, and findings of the watershed mapping program.

The soil erodibility factor (K), the cover index factor (C), and the practice factor (P) were all developed as part of the watershed mapping program for each of the identified mapping units. These units were delineated based on different criteria than the sub-basin units used for this portion of the study and therefore did not correspond directly to the sub-basins in the sediment yield model. Composite K, C, and P factors were developed for each sub-basin based on an weighted average of the values for each mapping unit within each sub-basin.

The slope length-gradient factor (LS) was estimated from Equation (2) using USGS 7.5' topographic quadrangle maps to determine the slope-steepness (S) and slope-length factor (λ). These factors were estimated using the techniques developed by Williams and Berndt. The slope-steepness factor is estimated using the contour-length method for computing average watershed slope by weighting the slope between contours according to the area between contours. The slope-length factor is estimated using the contour-extreme point method for computing average watershed slope length.

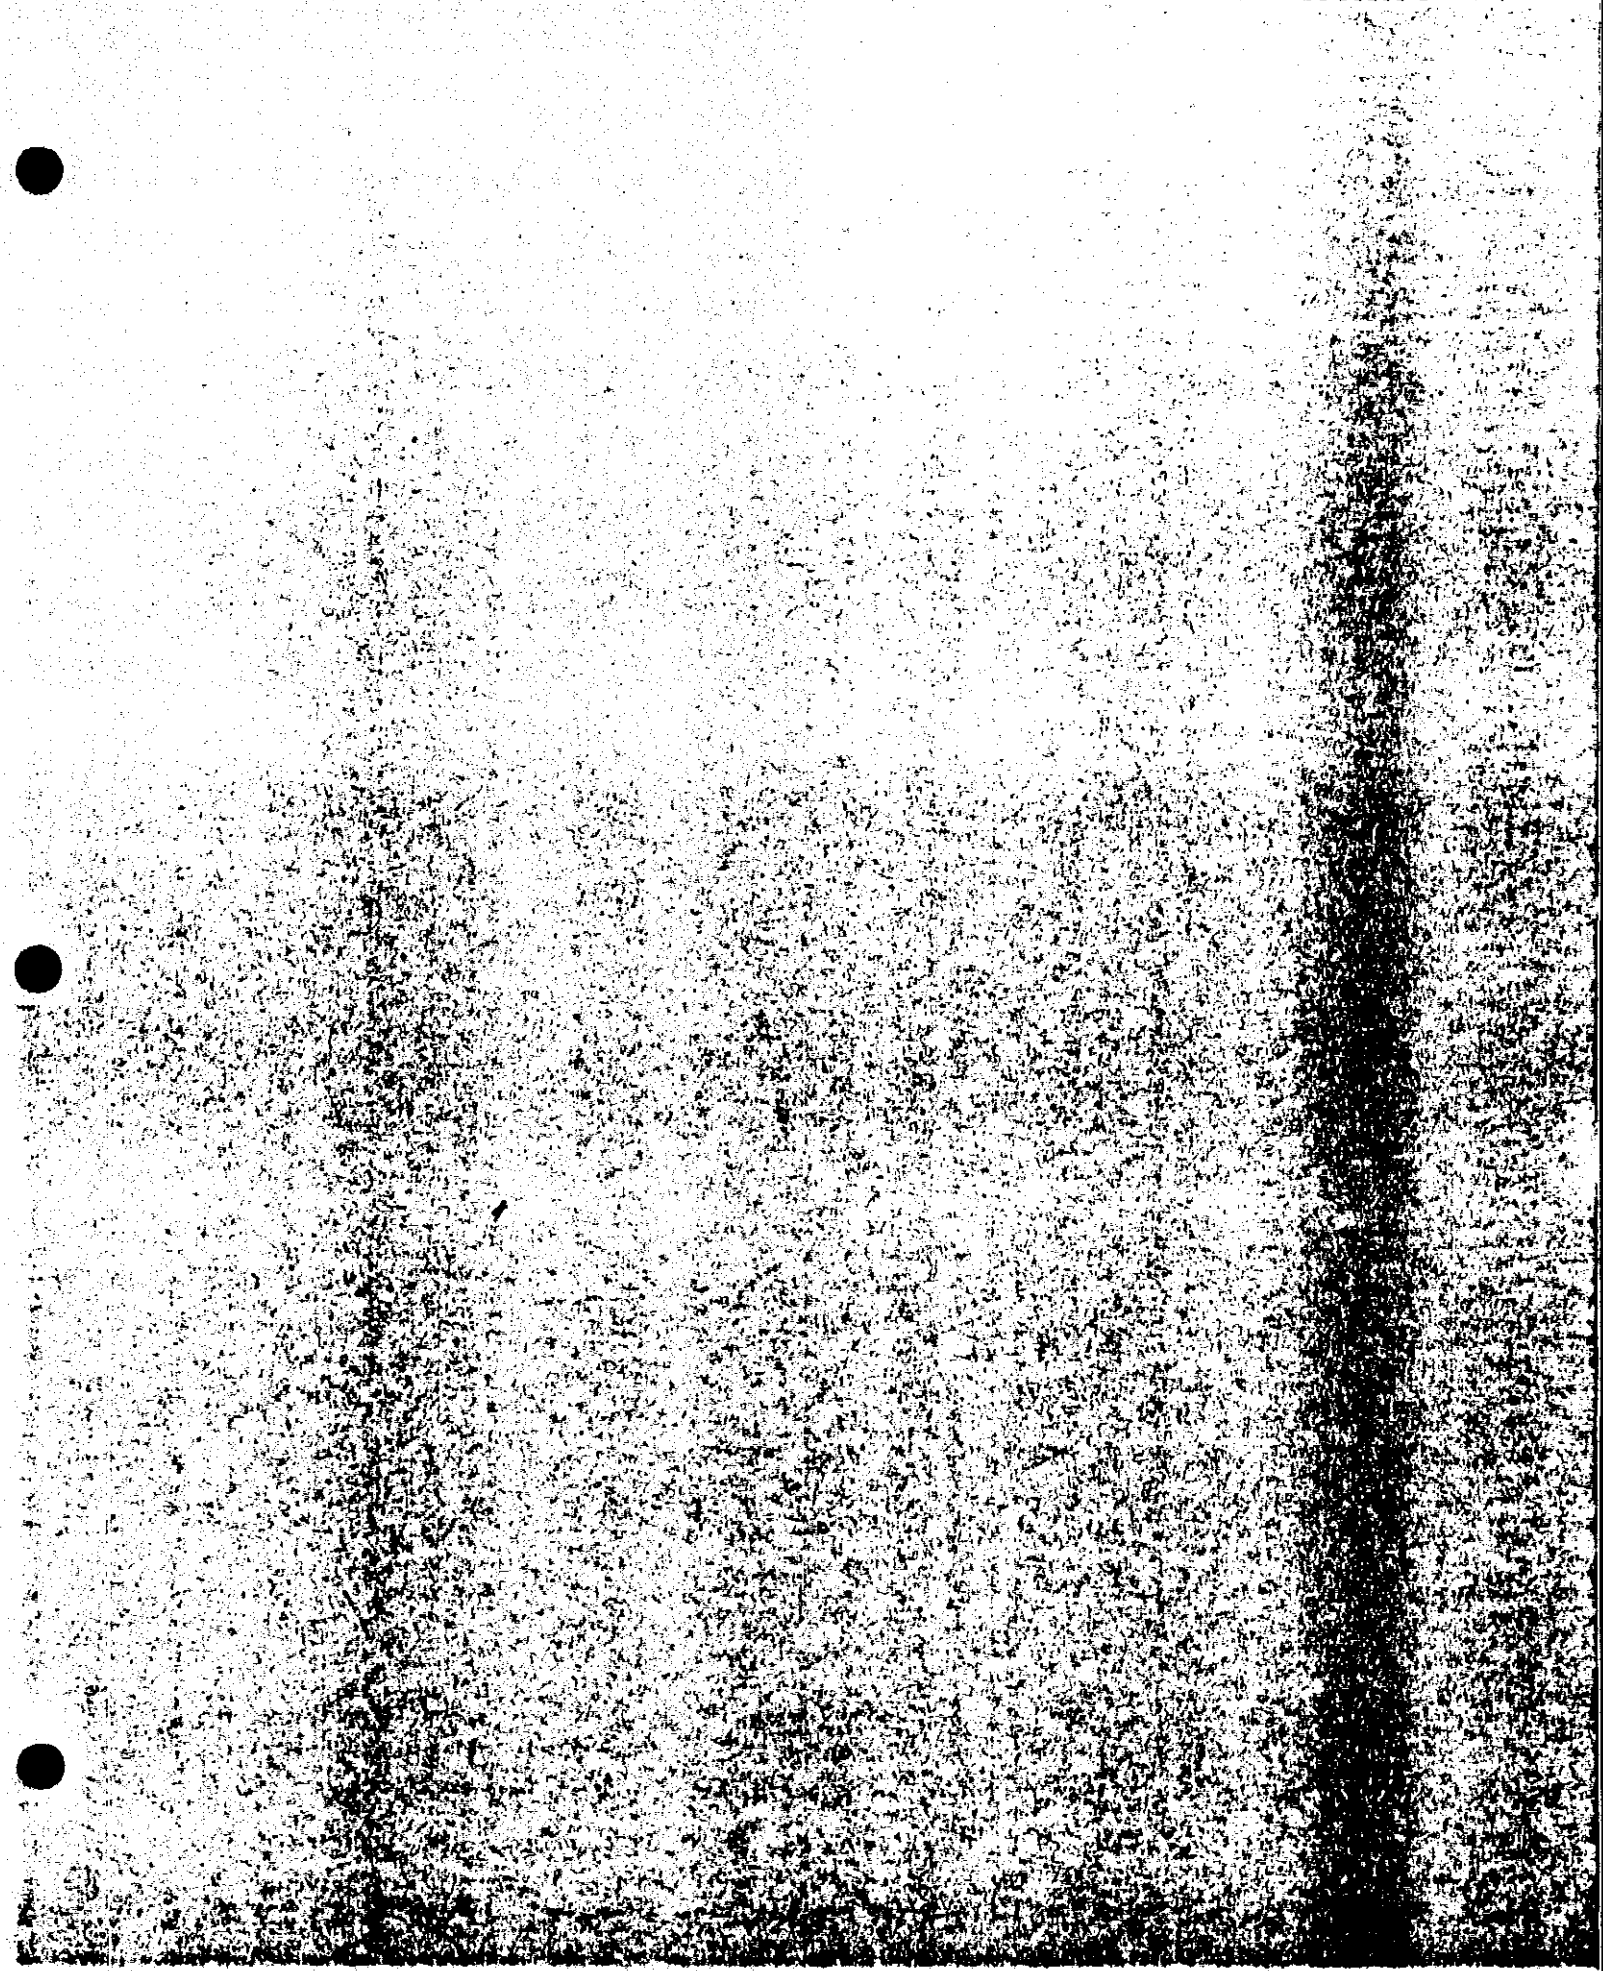
9. MODEL CONFIRMATION



MODEL CONFIRMATION

HEC-6 is a complex and comprehensive tool to model sediment transport. Its complexity results from the requirement that several assumptions be made. To verify that the results of HEC-6 were in fact consistent with the physical conditions being modeled, a simplified confirmation process was undertaken. This process uses a program developed by Dr. Richard French, a renowned expert in the field of alluvial fans and alluvial fan hydraulics.

Dr. French simulated three conditions which were compared with the results of HEC-6. Two conditions using very simplified input parameters were simulated using French's formulation of Yang's equation and HEC-6. The results of these two tests were very similar and confirmed that the algorithms used in HEC-6 are being properly applied.

A third case was simulated using French's formulation of Yang's equation and resulted in wide disparity with the results of HEC-6. Further evaluation identified that French's formulation applied the transport equations developed by Yang outside of the range to which they were originally intended. As a result, French's formulation predicted that significantly greater quantities of fine materials were being transported than were available from upstream sources. The mountainous (limestone) headwaters and the bed materials on the alluvial fan limit the amount of fine materials available for transport. Once again, this supported the use of HEC-6 as it appeared to more reasonably reflect the actual conditions found in the Range Wash basin.

MEMORANDUM

January 6, 1992

TO: Mark Glidden

FROM: R.H. French RHF

SUBJECT: Las Vegas Range Wash - Test of HEC-6

VIA FAX: (303)-987-3908

Per our telephone conversation of this afternoon, I am writing to provice you three examples to check the HEC-6 implementation of the Yang equations. The intention is to make the HEC-6 data files trivial and to test the code.

TEST 1: Rectangular channel with

Q = 2228 ft^3/s
y = 1.5 ft (depth of flow)
B = 210 ft (bottom width)
u = 7 ft/s
S = 0.02 ft/ft
nu = 0.0000106 ft^2/s (kinematic viscosity)
Sediment Size = 1.41 mm

My hand calculations for the above data suggest that the equilibrium load is (4205 tons/hr) assuming a specific gravity of 2.65. Within reason, if this load is input into the above defined channel, there should be neither deposition nor erosion. This will test the sand size equation.

TEST 2: Rectangular channel with the above channel geometry but the sediment size is 7.8 mm. For these data, my hand calculations estimate the equilibrium load as 157 tons/hr assuming a specific gravity of 2.65. This will test the gravel size equation. I would note here that one of my concerns is that in earlier USACE programs such as (722-F3-R0-09G) the Yang gravel transport formulation was not implemented; and further, no error message was implemented when sand sizes were specified. This program is still being provided users through vendors.

TEST 3: The size distribution forwarded me by Tom or

4.0-8.0	5.66	0.140	93.
8.0-16.	11.3	0.190	209.
16.-32.	22.6	0.175	327.
32.-64.	45.3	0.135	432.

The channel geometry and hydraulic data are as follows:

$Q = 6584\ ft^3/s$
$y = 2.85\ ft$
$u = 14.3\ ft/s$
$S = 0.010\ ft/ft$
$nu = 0.00001059\ ft^2/s$
Trapezoidal channel with b = 150 ft; z = 4

and a specific gravity of 2.65 is assumed.

My computer estimation is that the equilibrium sediment transport is 96,104,180 tons/hr. 2,306,500,320 ton/day I would note that of this load 93,442,370 tons/hour derives from the smallest size fraction. This last test should confirm the performance outside the original sizes for which the Yang equations were developed. This is not to say that the answers are correct only that we are obtaining the same answers.

I would expect that some differences in the load will be noted. This could be due to the implementation within HEC-6 of a code for the fall velocity. However, let us see what happens. I hope that I have provided you and Tom sufficient data to implement these tests. Given my experience with USACE programs these tests are very important.

I'll call you on Wednesday and hopefully see you on Friday.

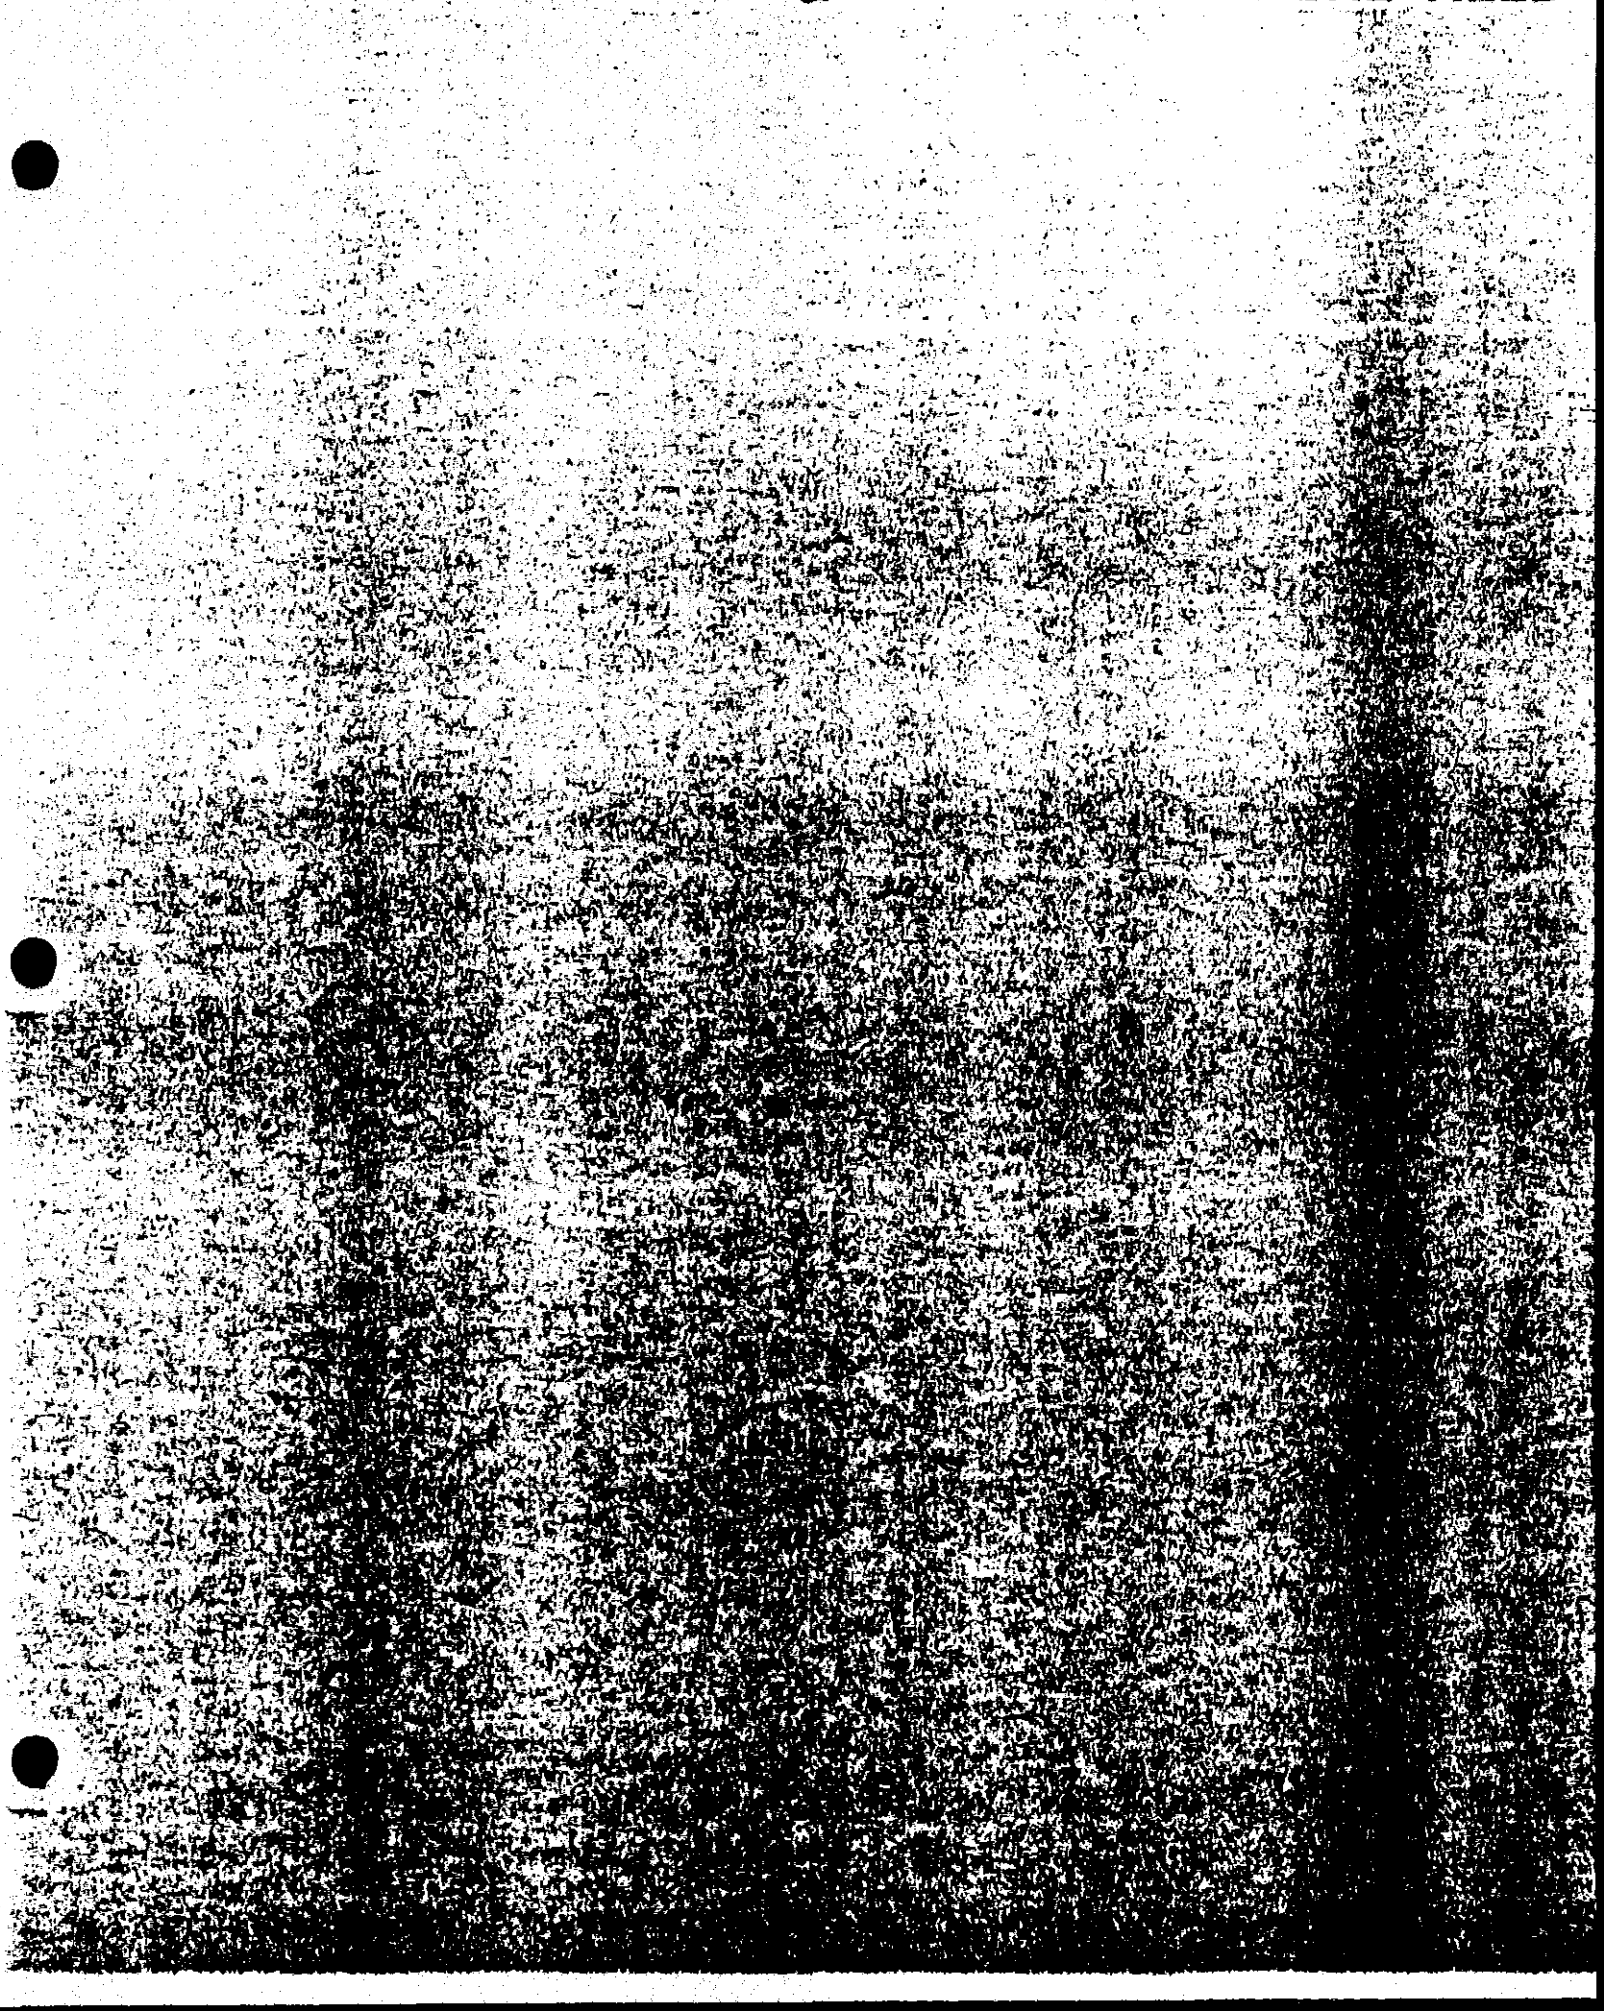
10. AVERAGE ANNUAL YIELD



AVERAGE ANNUAL SEDIMENT YIELD CALIBRATION

The determination of event specific yield was an interactive process as depicted on the attached flow chart. The first step was to estimate the various input parameters into HEC-6 and establish the equilibrium sediment transport at the location of the dike. These values were then integrated and compared to the average annual yield determined previously. If these values were within five percent this was assumed to be correct and was used for subsequent determinations.

The process of integrating event specific yields and determining an average annual yield has been documented for sediment transport studies as well as economic analyses and other applications. When used in a sediment transport analysis, discharges not related to a specific event must be considered. Commonly, an integration constant reflecting the relationship between the mathematical average of annual total runoff volume at the gage and the average annual runoff volume estimated using the integration process is computed. Two gages in the Las Vegas Valley were evaluated to determine the constant to be used in this analysis. A gage on the Las Vegas Wash at North Las Vegas resulted in a relationship of 1.2 while an analysis of the Flamingo Wash near Charleston Park resulted in a relationship of 1.3. Because the Flamingo Wash watershed was more similar to Range Wash in size, and integration constant of 1.3 was adopted for this analysis. The computations and gage analysis are attached in the "Integration Constant" section.

As previously discussed, the application of HEC-6 to an alluvial system cannot be accomplished without some manipulation to the methodology. The sharp rise and fall of the

unit hydrograph and the variation in channel cross section make it very difficult to appropriately simulate the alluvial fan transport characteristics. To better establish equilibrium transport for each event, an equilibrium sediment transport relationship was developed for each discharge and these were combined to estimate total discharge for the total hydrograph. This process is depicted in the detail on the flow chart.

The system was modeled using a fixed discharge and a fixed channel cross section related to that discharge based on Dawdy/FEMA. The equilibrium sediment transport for that discharge was then computed using HEC-6. This process was performed for several discharges. The results of these simulations is included in the "Equilibrium Constant" section. A rating curve was then developed which was a power curve function of the form $Q_{sed} = AQuarter^{B}$. The rating curve computations are attached in the "Computation of Annual Yield" section. Using this relationship, the hydrograph of the flood event was discretized and a specific sediment discharge computed for each time step in the hydrograph. This is presented in the same section. It was then possible to sum the sediment volume for each time step over the entire storm and develop a total transport volume which represents an event specific sediment yield. These individual event values were then integrated and the integration factor applied to develop an average annual yield. These were compared to the PSIA estimate of average annual sediment and input parameters adjusted until an appropriate match was achieved. The integration is summarized and show on the final pages of this section.

The results of the calibration and integration process resulted in the following conclusions:

- o A roughness coefficient of .022 is appropriate
- o Water temperature of 70^{O} F is appropriate
- o A particle size distribution of 30/70 (fines/coarse) results in a appropriate estimation of average annual yield
- o The integration constant of 1.3 is supportable from gage records
- o The integrated volume sediment yield is 15.2 AF (within five percent of target 16 AF)
- o The 100-year event yield of 147 af is approximately 9.5 times the average annual yield (reasonably close to the assumed 7)

The runs attached at the end of this section provide several useful pieces of information. First and foremost, the runs indicate that the integration process has defined inflow characteristics at the apex of the fan which result in an average annual yield consistent with estimates. They also provide the basis for the inflow sediment rating curves used in the subsequent analyses. Because alluvial fan flows have reached equilibrium when they reach the dike, these models can be used to simulate the transition from fan to dike. They also establish the particle size distribution of inflows into the system.

09419677 FLAMINGO WASH AT MRLND PARKWAY, AT LAS VEGAS, NV

LOCATION.--Lat 36:08:35, Long 115:04:12, Hydrologic Unit 15010015.

DRAINAGE AREA.-- 106.00 mi2 (274.54 km2).

PERIOD OF RECORD.-- 1970-1989

GAGE.-- Altitude of gage is 1976.60 ft(602 m).

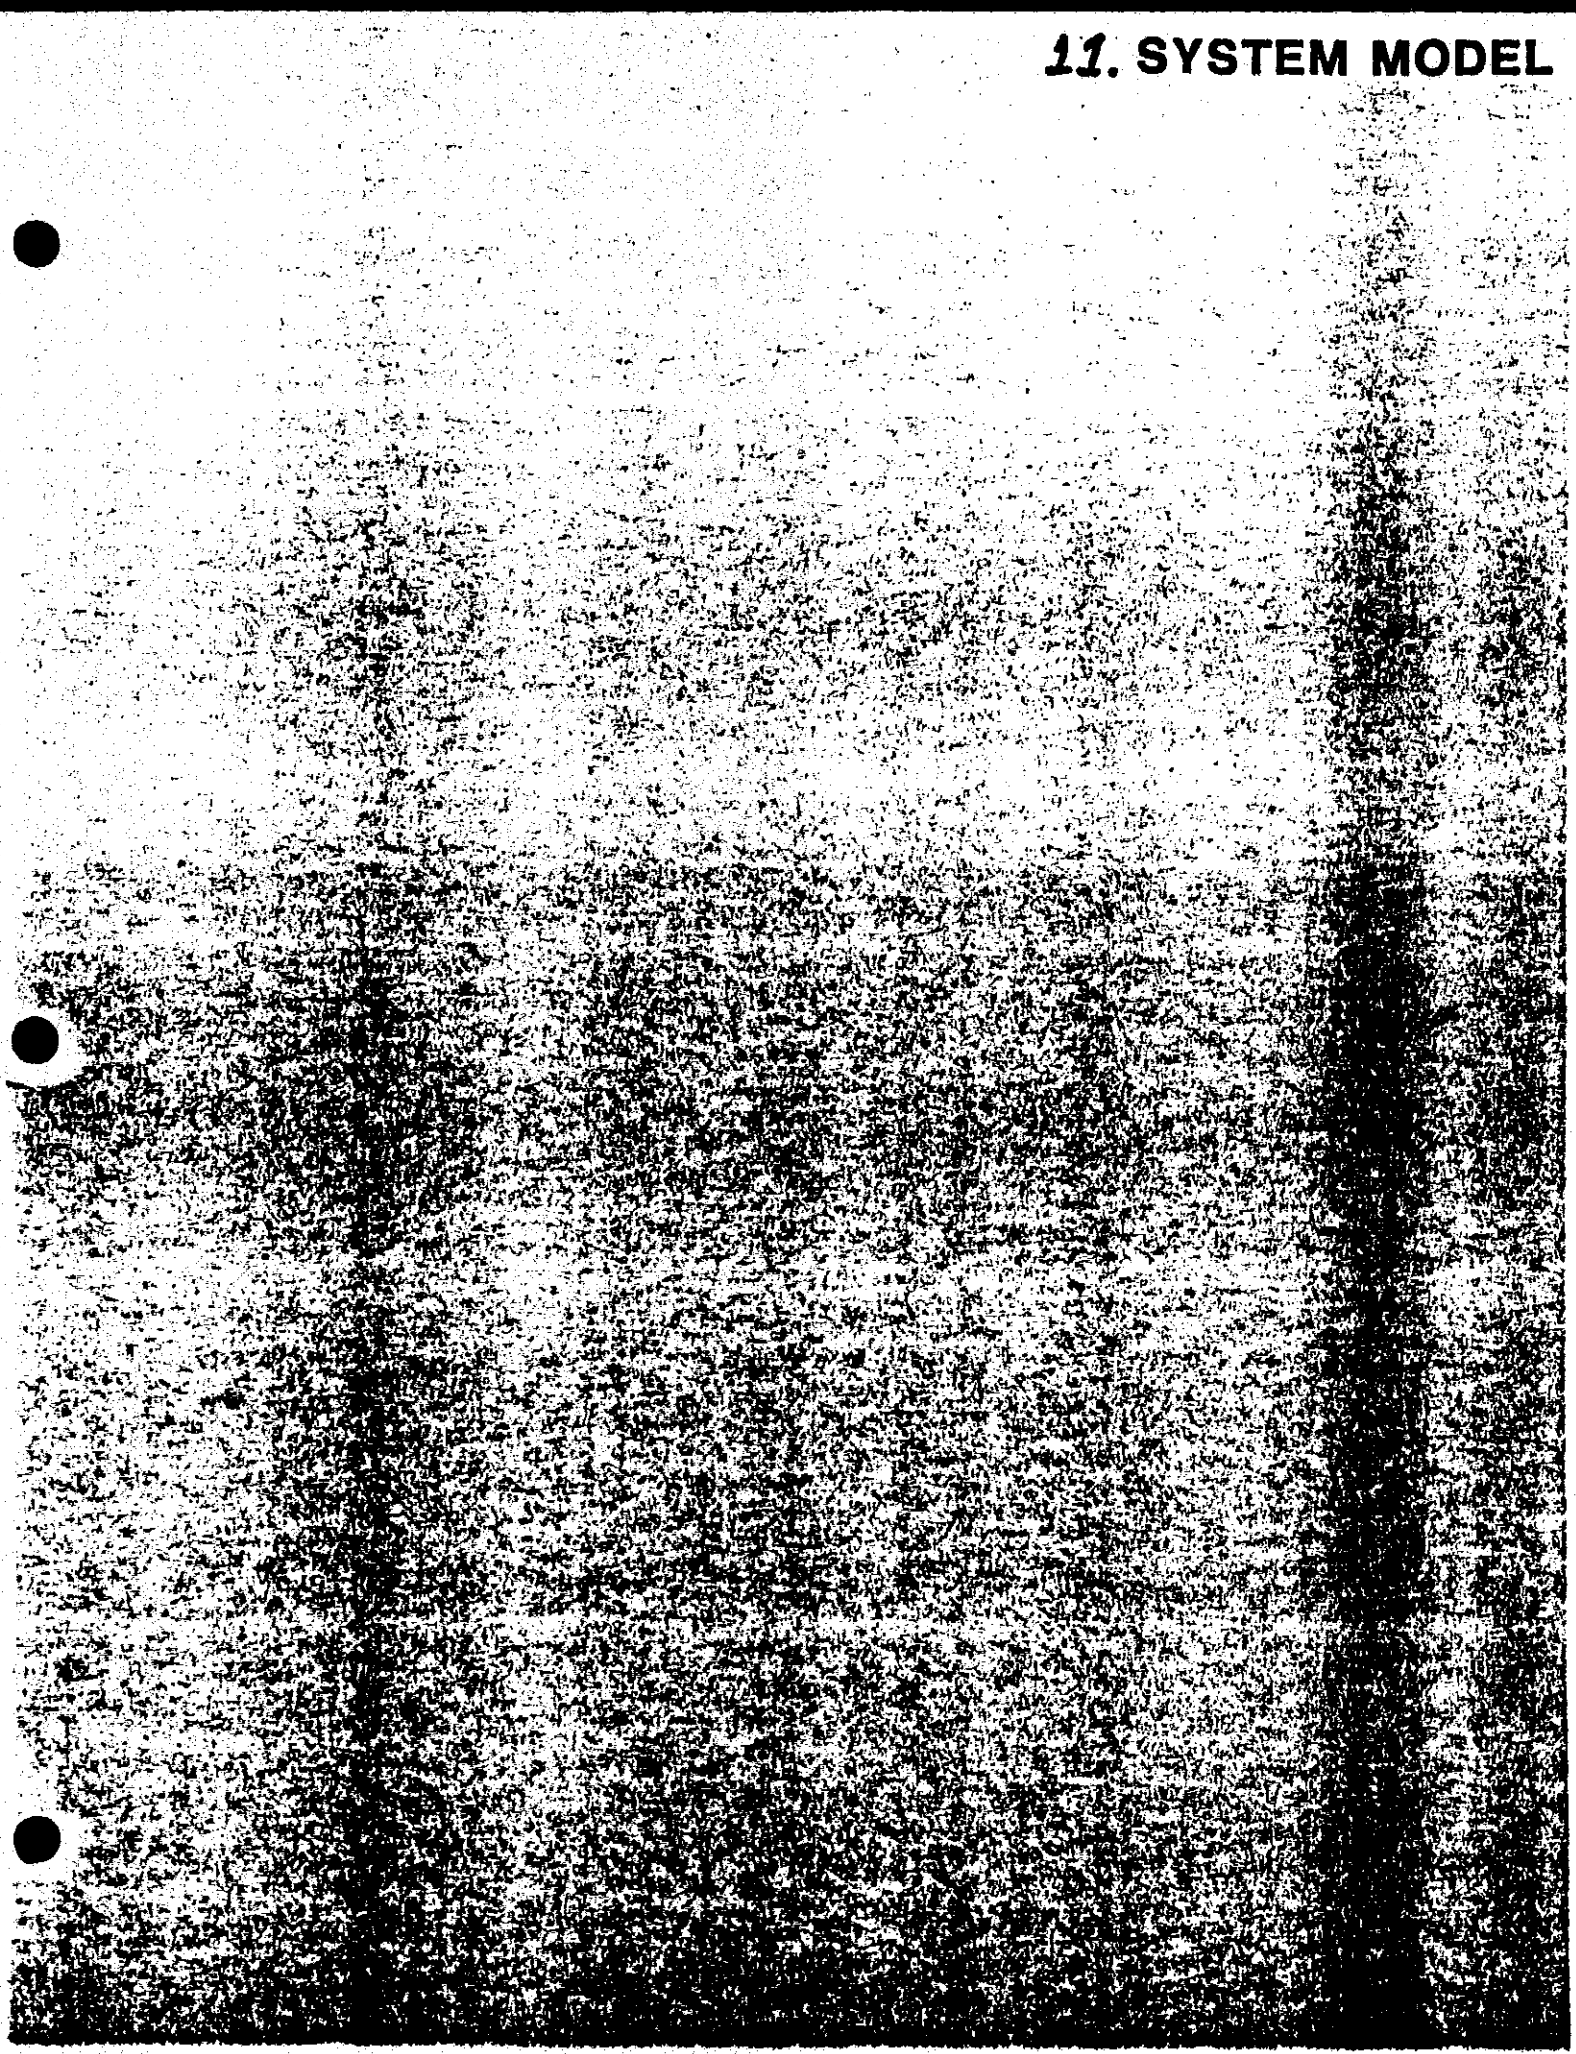
11. SYSTEM MODEL



SYSTEM MODEL

To simulate the system of alluvial fan and dike flows, an extension of the alluvial fan surface model was developed. This model represents the transition from flow down the fan to flow along the diversion dike. To identify the worst case scenario several specific alternatives were investigated:

- o Fan surface to dike at a 1.0% slope
- o Fan surface to dike at a 0.5% slope

As is expected, the most critical case is the alluvial fan flows transitioning to flow along the dike at a 0.5% slope. Two key assumptions were made in the modeling of this system to reflect actual physical conditions:

- o The portion of the model representing fan flows assumed that flow for the entire hydrograph was in a channel with a width equal to Dawdy's 100-year channel width of 330 feet. Sensitivity runs were executed and it was determined that this was not a sensitive parameter. The total transport of sediment was less than 10 percent different when using a channel width of 100 feet versus the 100-year width of 330 feet. The wider channel width resulted in slightly more conservative results and was used in the analysis.

- To minimize the mathematical instability of the transition from fan to dike, a transition length of 1,000 feet was assumed. As previously mentioned, the HEC-6 model does not simulate abrupt changes in geometry without some mathematical instabilities. The critical information to be determined from the analysis is the absolute difference in the sediment carrying capacity between the fan and the dike at equilibrium, therefore, the length of the transition is not critical. It does, however, dampen some of the mathematical instability. The results of this analysis are attached hereto. A total volume of sediment deposited in the transition from alluvial fan to dike was computed. This was used in subsequent steps to determine the dike height. The computed total deposition was 65,000 tons.

12. DEPOSITION PERCENTAGE

DEPOSITION PERCENTAGE

During the course of the analysis, certain mathematical instabilities were identified within HEC-6. The computed instantaneous transport capacity at a particular section would oscillate above and below the final equilibrium capacity. At the end of the hydrograph and also farther downstream, these oscillations had been dampered sufficiently to have reach stability. As such, the results from HEC-6 could not be used directly to determine the channel invert elevation or the amount of instantaneous deposition at the time of the 100-year peak discharge. Therefore, an intermediate series of computation had to be performed.

A form of the integration approach was utilized to estimate total deposition at the time of the 100-year peak. The difference in equilibrium transport capacity of flows on the fan and those along the dike was determined several times throughout the hydrograph. These points were plotted and a deposition rate versus time curve was developed. The area beneath the curve represents the total deposition and that portion of the curve which lies before the peak discharge represents deposition at the time of the 100-year peak. A tabulation of the results was prepared. Using this analysis it was determined that 37 percent of the total deposition had occurred at the time of the peak discharge. This value represents the amount of sediment which is distributed through the transition reach when peak channel flows occur.

TRANSITION MODEL

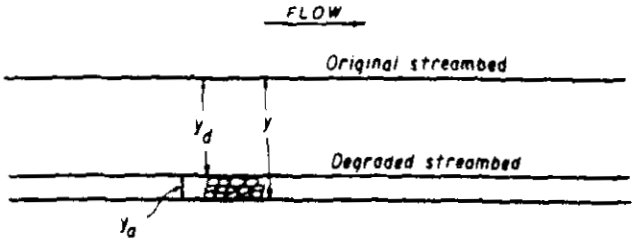
The computation of sediment transport through the transition from alluvial fan flow to dike flow presents considerable difficulties using HEC-6. As previously mentioned, HEC-6 has computational difficulties modeling sediment transport through changes in channel geometry and flow rate. The mathematical instabilities make it difficult to compute the actual amount of deposition occurring at a specific time and at a specific location. That is compounded by the difficulty in predicting the horizontal changes in channel alignment occurring coincident with the deposition. The unique conditions make the application of HEC-6 very difficult.

As a result of the aforementioned conditions, an alternative approach to model the changes in sediment transport and the resulting deposition along the transition from fan flows to flows along the dike was adopted. This methodology relies on work done by the Bureau of Reclamation on general scour below dam outlet structures. The geometry of channel scour is similar to the geometry of deposition. A copy of the Bureau of Reclamation channel degradation analysis copied from Design of Small Dams is attached hereto. The assumptions used in adapting this methodology to the case of transition deposition is also included.

The geometry of the deposition is a function of total deposition volume and of the width of the channel. Since peak discharges are of interest, the volume of deposition which has occurred at the time of the peak is used in these computations. This volume will be superimposed on the channel invert and an appropriate dike height for the 100-year discharge will be computed. An average of the alluvial fan channel and the diversion dike channel was used in the computations. Using this information, a maximum depth of deposition of 5.64 feet is computed

and a horizontal distance of 1,050 feet is computed. The deposition was determined to fit a vertical parabolic curve as described by the Bureau of Reclamation.

Appendix H
B. Downstream Channel Effects
H-4 Channel Degradation



y_d = Depth of degradation

y_a = Armoring layer

Figure H–15. Armoring definition sketch. 288–D–2856.

The size analysis of streambed material shown in figure H–16 is also available. Computed armoring sizes, D_a, are:

(1) $V_b = 0.7(3.4) = 2.4$
From figure H-13 $D_a = 22$ mm.

(2) $T.F. = 62.4(4.0)(0.0021) = 0.52$ lb./ft.^{2}
From figure H-14 $D_a = 31$ mm.

(3) $D_a = \dfrac{5.26(0.0021)(4.0)}{(0.03/(34)^{1/6})^{3/2}} = 20$ mm.

(4) $D_a = \dfrac{4762(0.0021)^{4/3}.500}{60} = 11$ mm.

A mean of the above armoring sizes is 21 mm., which was adopted as a representative armoring size. By use of equation 21 and figure H–16, the depth of degradation is:

$$y_a = 3\ D_a = 3(21) = 63 \text{ mm. or } 0.206 \text{ ft.}$$

$$y_d = 0.206\left(\frac{1}{0.19} - 1\right) = 0.9 \text{ ft.}$$

(d) *Degradation Limited by a Stable Slope.*—This method is based on the limiting or stable slope which will result in no transport of the material forming the bed of the stream channel, and is used where there is not enough coarse material available to form an armor on the channel bed. The stable slope can be computed for a river reach using equations 13 and 14.

In addition to the limiting or stable slope of the degraded channel, it is also necessary to determine the volume of material that can be expected to be removed from the channel. If there are no downstream channel controls that could limit degradation, it is sometimes assumed that the river will pick up a load of coarse sediment (>0.0625 mm.) equal to that portion of the historic load in the same size range. This necessarily assumes little depletion in quantity of streamflow and minor regulation by the upstream reservoir. If the streamflow is significantly depleted or regulated, the sediment load to be picked up will be less than the historic load and appropriate adjustments in the load to be picked up will have to be made.

Having determined the stable slope and the volume of material that can be expected to be removed, the depth of degradation at the dam and the degraded channel profile can be estimated if the following assumptions can be reasonably well satisfied:

(1) The degradation reach is sufficiently uniform to permit the use of average cross sections and slope throughout the reach.
(2) The bed and bank material throughout the reach is similar enough that an average composition can be used and that there are no existing nonerodible barriers in the bed or banks to prevent the stream from attaining the average stable section at the stable slope.
(3) The degradation will be such that the vertical component will predominate and horizontal movement will be limited to bank sloughing resulting from the vertical degradation.

Experience has shown that a degraded stream profile can be represented by a typical three-slope arrangement, as shown in figure H–17 [23]. The derivation of the formulae for the longitudinal area, A_T, and the degradation reach length, L, are included in the figure. The previously determined volume may be expresed by:

$$V = \frac{A_T B}{43{,}560} \qquad (22)$$

where

V=volume of material to be degraded in acre-feet

A_T=longitudinal area of degradation in square feet

B=degraded channel width in feet.

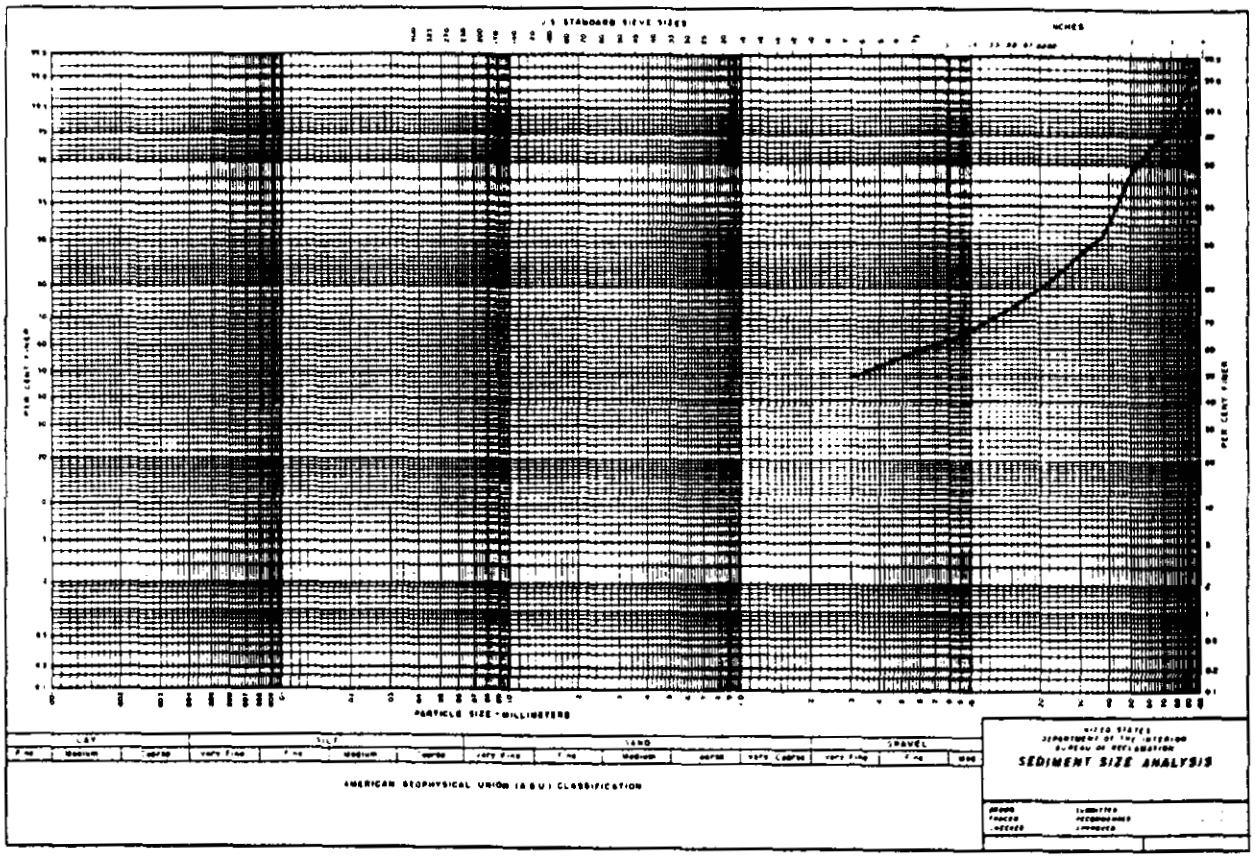


Figure H–16. Bed material size analysis. 288–D–2857.

By rearranging equation 22 the longitudinal area may be found:

$$A_T = \frac{43{,}560\ V}{B} \tag{23}$$

Once a value has been found for A_T, the depth of degradation may be computed using the following equation:

$$D = \left(\frac{64\ A_T \Delta S}{39}\right)^{1/2} \tag{24}$$

where ΔS=the difference between the existing slope and the stable slope and the length of the degraded reach can be computed by:

$$L = \frac{13\ D}{S \Delta S} \tag{25}$$

If it is anticipated that lateral degradation will be a significant factor, additional study will be necessary to determine the degraded channel width. Because part of the material will be coming from the stream banks, the extent of vertical degradation will ordinarily not be as great. Lateral movement should always be suspect when the banks are composed of the same material as the bed and there is not a great deal of vegetation to hold them. References [25] and [26] are recommended as guides when these conditions prevail.

If a permanent control exists at some point within the degradation reach, equation 25 may be used to solve for the depth of degradation directly.

As an example of degradation computations when the stable slope controls, the following

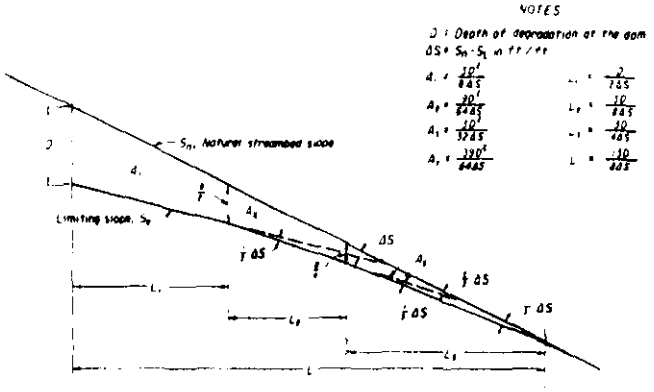

Figure H-17 Degraded channel by the three-slope method. 288-D-2858.

data are known about a river channel below a diversion dam:

Dominant discharge	$=Q=780$ c.f.s.
Channel width	$=B=350$ ft.
Mean channel depth	$=d=1.05$ ft.
Existing stream gradient	$=S_n=0.0014$
Bed material—$D_m=D_{50}$	$=0.3$ mm.
D_{90}	$=0.96$ mm.
Manning's n value	$=0.027$.

It was computed that 2,160 acre-feet of sand would deposit behind the diversion dam during the 100-year economic life of the structure, and that an equal volume of sand would be eroded from the downstream channel.

The stable slope computations are:

$$S_1=\left(\frac{0.00021\,(0.3)\,(350)}{780}\right)^{1.4}=0.000387$$

and

$$S_1=\frac{0.19[0.027/(0.96)^{1/6}]^{3/2}\,0.3}{1.05}=0.000244$$

(Q/Q_n is assumed equal to unity)

A mean of the two computed slopes is 0.000315 and it is assumed to be the stable slope. The difference between the existing and degraded slope, ΔS, is 0.001085.

The longitudinal degradation area is:

$$A_T=\frac{43{,}560\,(2{,}160)}{350}=268{,}830\text{ ft.}^2,$$

the depth of degradation at the dam is:

$$D=\left(\frac{64\,(268{,}830)\,(0.001085)}{39}\right)^{1/2}=21.9\text{ ft.},$$

and the length of the degradation reach is:

$$L=\frac{13\,(21.9)}{8\,(0.001085)}=32{,}800\text{ ft.}$$

WATER SURFACE PROFILE DETERMINATION

Using the deposition depth, the computed geometry and the peak discharge, a HEC-2 water surface profile computation was performed. This analysis was performed for both the subcritical and supercritical condition. It was determined that the critical location was in the subcritical run at a section along the dike at which the depth of flow was 4.4 feet and the velocity head was 2.3 feet. This value was very similar to the subcritical profile at which the depth of flow was 4.6 feet and the velocity head of 2.1 feet. In both cases, the total energy head was 6.7 feet which was the basis for the dike height computation.

DIKE HEIGHT COMPUTATION

The height of the dike was determined by the sum of the following components:

o	Deposition	=	5.6 feet
o	Depth of flow	=	4.4 feet
o	Velocity head	=	2.3 feet
o	Freeboard	=	3 feet
	Total Dike Height	=	15.3 feet

This represents the most conservative combination of all of the factors together. It presumes that the entire deposition has occurred along the toe of the dike. Because of the horizontal transition, it is likely that this deposition will occur at some distance remote from the dike and at the dike the deposition is likely to be substantially less. Once again, limitations of the HEC-6 model render it unable to determine the form of the horizontal transition. Therefore, for the purpose of computation, we have assumed that the actual flow is in a straight alignment and that all deposition would occur at the toe of the dike. This is a conservative assumption.

We have evaluated the impact of alluvial fan flows striking the dike at a 90^{o} angle. The effect of fan flows impacting the dike perpendicular to its alignment is not the most critical assumption. As identified in the HEC-2 computation, the total energy head of fan flows is approximately 5.8 feet. The total energy head of flows along the dike is 6.6 feet. This indicates that more energy is required to force flows in a longitudinal direction along the dike than to drive flows down the fan. The total energy head of 6.6 feet used in the dike height determination allows for the water

to develop sufficient head to drive it in the downstream direction. Once again, this is an extremely conservative assumption in that the channel width and required energy head is likely to be less at the location of maximum deposition.

In addition to the degree of conservatism associated with the deposition computation and the total energy head computation, a three-foot freeboard is superimposed on those values to reflect FEMA freeboard for levee systems. The combination of this freeboard with the conservative estimates of energy head and deposition result in a dike of sufficient height to meet FEMA requirements.

Attention: Mr. Walter Hines

Subject: Addendum No. 2
Additional Slope Stability Analysis
Range Wash Flood Control Project
North Las Vegas, Nevada

Gentlemen:

INTRODUCTION

This report presents the results of our slope stability analysis conducted for the new profile of the Range Wash Flood Control Project located near Range Road in North Las Vegas, Nevada. This study was performed in general accordance with our signed confirmation letter dated February 3, 1992. Geotechnical recommendations relative to this project were provided in our Geotechnical Investigation report, dated January 8, 1992 (CCSW Project No. 91-33298-01). The findings and conclusions of this study supplement those provided in the previous report.

We understand that the dike will be 15.2 feet in height above the earthern channel bottom, and that the soil-cement facing on the upstream face of the dike may not be used. A 3:1 (horizontal to vertical) slope is planned for the downstream slope, and a 4:1 (horizontal to vertical) for the upstream face of the dike. We also understand that the crest width of the dike is 12 feet, and the water depth within the channel is on the order of 10 feet.

SLOPE STABILITY ANALYSIS

The stability analyses were conducted in general accordance with the Nevada State Statutes, the Clark County Regional Flood Control District "Hydrologic Criteria and Drainage Design Manual." The anticipated maximum dike slope sections were analyzed for four separate cases; (1) end of construction, (2) sudden drawdown, (3) steady state seepage, and (4) seismic analysis under steady state seepage. The dike was analyzed for a height of 15.2 feet with 10 feet of impounded water. The computer program SB-Slope, Version 3.0, developed by von Gunten Engineering Software, Inc. was used to calculate the minimum factor of safety by Bishop's simplified method of slices for circular failure surfaces. Based on

previously performed laboratory tests, an average saturated angle of internal friction of 38 degrees, and a cohesion intercept of zero, were used, for both the foundation soil and the compacted embankment. A summary of the minimum acceptable factors of safety, and calculated factors of safety is presented in the following table. The results of the slope stability analyses are presented in Appendix A.

Calculated and Required Factors of Safety for Slope Stability

Loading Condition	Case	Required[1] F.S.	Calculated F.S.
End of Construction	1	1.3	2.5
Sudden Drawdown	2	1.2	1.8
Static-Steady State Seepage	3	1.5	1.7
Seismic-Steady[2] State Seepage	4	1.0	1.4

[1] In accordance with the "Recommended Guidelines for Safety Inspection of Dams" published by the Corps of Engineers (1973).
[2] Seismic evaluation was based on pseudo-static analysis with seismic coefficient of 0.05.

It has been our pleasure to be of continued service to you on this project. If you have any questions, please contact this office.

IMPORTANT INFORMATION
ABOUT YOUR
GEOTECHNICAL ENGINEERING REPORT

More construction problems are caused by site subsurface conditions than any other factor. As troublesome as subsurface problems can be, their frequency and extent have been lessened considerably in recent years, due in large measure to programs and publications of ASFE/ The Association of Engineering Firms Practicing in the Geosciences.

The following suggestions and observations are offered to help you reduce the geotechnical-related delays, cost-overruns and other costly headaches that can occur during a construction project.

A GEOTECHNICAL ENGINEERING REPORT IS BASED ON A UNIQUE SET OF PROJECT-SPECIFIC FACTORS

A geotechnical engineering report is based on a subsurface exploration plan designed to incorporate a unique set of project-specific factors. These typically include: the general nature of the structure involved, its size and configuration; the location of the structure on the site and its orientation; physical concomitants such as access roads, parking lots, and underground utilities, and the level of additional risk which the client assumed by virtue of limitations imposed upon the exploratory program. To help avoid costly problems, consult the geotechnical engineer to determine how any factors which change subsequent to the date of the report may affect its recommendations.

Unless your consulting geotechnical engineer indicates otherwise, *your geotechnical engineering report should not be used*:

- When the nature of the proposed structure is changed, for example, if an office building will be erected instead of a parking garage, or if a refrigerated warehouse will be built instead of an unrefrigerated one;
- when the size or configuration of the proposed structure is altered;
- when the location or orientation of the proposed structure is modified;
- when there is a change of ownership, or
- for application to an adjacent site.

Geotechnical engineers cannot accept responsibility for problems which may develop if they are not consulted after factors considered in their report's development have changed.

MOST GEOTECHNICAL "FINDINGS" ARE PROFESSIONAL ESTIMATES

Site exploration identifies actual subsurface conditions only at those points where samples are taken, when they are taken. Data derived through sampling and subsequent laboratory testing are extrapolated by geotechnical engineers who then render an opinion about overall subsurface conditions, their likely reaction to proposed construction activity, and appropriate foundation design. Even under optimal circumstances actual conditions may differ from those inferred to exist, because no geotechnical engineer, no matter how qualified, and no subsurface exploration program, no matter how comprehensive, can reveal what is hidden by earth, rock and time. The actual interface between materials may be far more gradual or abrupt than a report indicates. Actual conditions in areas not sampled may differ from predictions. *Nothing can be done to prevent the unanticipated, but steps can be taken to help minimize their impact.* For this reason, *most experienced owners retain their geotechnical consultants through the construction stage*, to identify variances, conduct additional tests which may be needed, and to recommend solutions to problems encountered on site.

SUBSURFACE CONDITIONS CAN CHANGE

Subsurface conditions may be modified by constantly-changing natural forces. Because a geotechnical engineering report is based on conditions which existed at the time of subsurface exploration, *construction decisions should not be based on a geotechnical engineering report whose adequacy may have been affected by time.* Speak with the geotechnical consultant to learn if additional tests are advisable before construction starts.

Construction operations at or adjacent to the site and natural events such as floods, earthquakes or groundwater fluctuations may also affect subsurface conditions and, thus, the continuing adequacy of a geotechnical report. The geotechnical engineer should be kept apprised of any such events, and should be consulted to determine if additional tests are necessary.

GEOTECHNICAL SERVICES ARE PERFORMED FOR SPECIFIC PURPOSES AND PERSONS

Geotechnical engineers' reports are prepared to meet the specific needs of specific individuals. A report prepared for a consulting civil engineer may not be adequate for a construction contractor, or even some other consulting civil engineer. Unless indicated otherwise, this report was prepared expressly for the client involved and expressly for purposes indicated by the client. Use by any other persons for any purpose, or by the client for a different purpose, may result in problems. *No individual other than the client should apply this report for its intended purpose without first conferring with the geotechnical engineer. No person should apply this report for any purpose other than that originally contemplated without first conferring with the geotechnical engineer.*

OTHER TOPICS

Slug Flow

The Clark County Regional Flood Control District Design Manual requires that slug flow conditions be considered in open channels flowing at high velocity. Slug flow was reviewed for flow along the dike and was determined not to be a problem. Slug flow exists if Froude numbers exceed 2. Flows in the Range Wash fan/dike system result in Froude numbers less than 1.4 and therefore indicate slug flow is not a critical design consideration.

Superelevation

Superelevation in horizontal curves has been evaluated as part of the sizing of the dike. It was determined that the maximum superelevation likely is .64 feet. This was assumed to occur along curves in the dike alignment where maximum deposition would not occur. Maximum deposition occurs at the transition from fan to dike. Superelevation in this region is not expected. The channel has been sized with a provision for freeboard which includes consideration of the energy head depth of flow and deposition since superelevation is not likely to occur coincident with maximum deposition, superelevation has not been included as a freeboard component.

SLUG FLOW

FROM — CLARK COUNTY REGIONAL FLOOD CONTROL DISTRICT, DESIGN MANUAL (10/90)

SLUG FLOW ≡ series of shallow water shock waves which occur in steep supercritical channels.

The concern is for the overtopping of freeboard, and therefore all channels should be designed to avoid slug flow.

WHEN $F > 2.0$, $S < 12/Re$ where: F = Froude #
S = slope (ft/ft)
$Re = VR/\nu$

IF $F < 2.0$, SLUG FLOW SHOULD NOT OCCUR

where: V = Design velocity (ft/s)
R = Hydraulic radius (ft)
ν = Kinematic viscosity (ft^2/s)

$$F = \frac{V}{\sqrt{gL}}$$

CASE 1: $Q = 6584$ cfs
$S = 0.5\%$
$B = 120$ ft
$V = 11.37$ ft/s
$D = 4.34$ ft

$$F = \frac{11.37}{\sqrt{32.2(4.34)}} \cong .96 \quad \text{(clearwater)}$$

CASE 2: $Q = 6589$ cfs
$S = 1.0\%$
$B = 120$ ft
$V = 14.61$ ft/s
$D = 3.45$ ft

$$F = \frac{14.61}{\sqrt{32.2(3.45)}} \cong 1.39 \quad \text{(clearwater)}$$

∴ SLUG FLOW SHOULD NOT OCCUR

⑤ Plot of point is well below slug flow zone

No slug flow

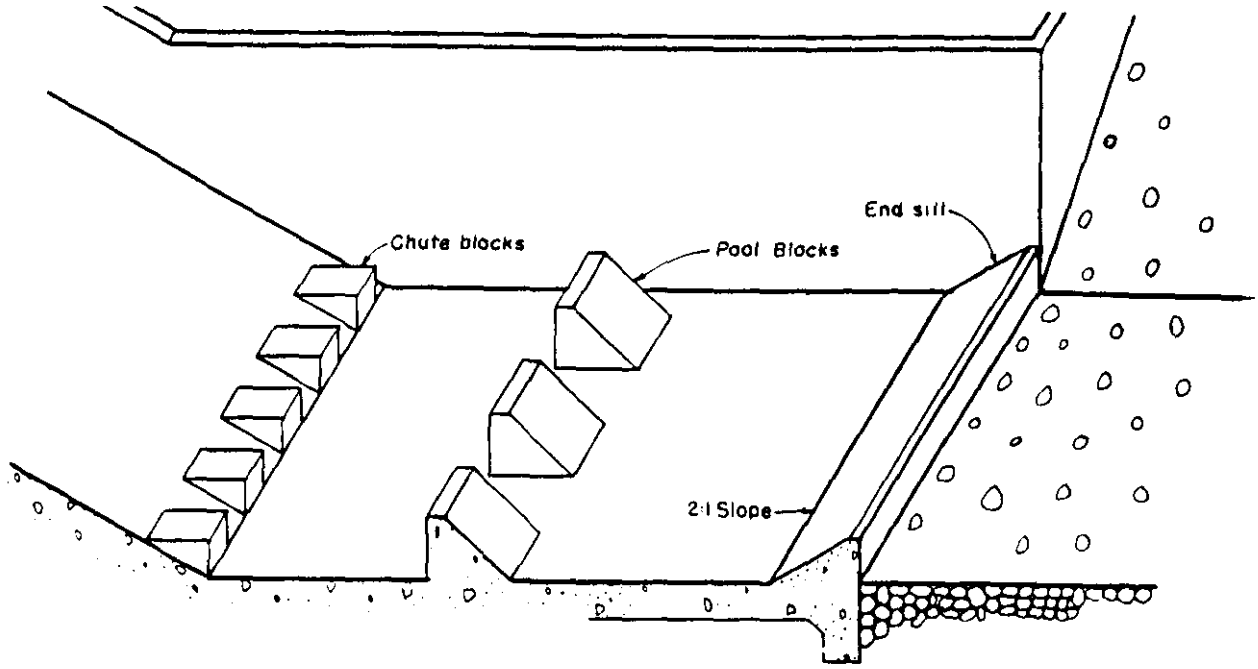

Figure 2-40. **Stilling pool with end sill. 103-D-1277**

Figures 2-45 and 2-46 have been developed to predict the possibility of slug flow occurring in a chute. The use of the figures requires the following operations:

(1) Divide the chute into a number of reaches as shown on figure 2-47. Point 1 should be at the beginning of the chute section.

(2) Using equation (6) or (7), with Q equal to 0.2, 0.5, and 1.0 times design Q, compute the water depth and energy levels at the points along the chute section that are to be checked for slugging. Use Manning's n = 0.010.

Figure 2-41. **Surging in a stilling pool caused by unstable flow in a chute structure. P222-117-36223**

(3) Determine sL for the point to be checked (fig. 2-47).

(4) At the points to be considered:

a. Compute the Vedernikov number ($\underline{V}$) [10].

$$\underline{V} = \frac{2}{3} \times \frac{b}{wp} \times \frac{V}{\sqrt{gd \cos\theta}} \qquad (10)$$

b. Compute the square of the Montuori number ($\underline{M}$) [11].

$$\underline{M}^2 = \frac{V^2}{g\, sL \cos\theta} \qquad (11)$$

In equations (10) and (11)

b = bottom width of the chute section

d = average water depth in the chute section:

$$d = \frac{\text{Area of the water prism}}{\text{Top width of the water prism,}}$$

Figure 2-42. **Pulsating flow in steep chute. Flow is 57 cfs. P222-117-36208D**

Figure 2-43. **Unstable flow at shallow depth. H-686-55D**

g = acceleration of gravity,
L = length of reach under consideration,
s = average slope of the energy gradient.

$$s = \tan \theta .$$

V = velocity,
wp = wetted perimeter of the section, and
θ = angle of inclination of the energy gradient.

(5) Plot the computed values on figure 2-45. If the plotted points fall within the slug flow zone, intermediate points may be checked to determine the point at which the waves begin to form.

(6) Compute the shape factor for the chute section.

$$\frac{d}{wp}$$

(7) Plot the computed value of $\frac{d}{wp}$ against the slope of the energy gradient, s, on figure 2-46.

Waves are not likely to be generated in the structure, unless the plotted data falls within the slugging zone on both figures 2-45 and 2-46.

If the charts indicate that slug flow will occur, the design may be modified to reduce the probability of waves being generated or the structure may be adapted to accommodate the

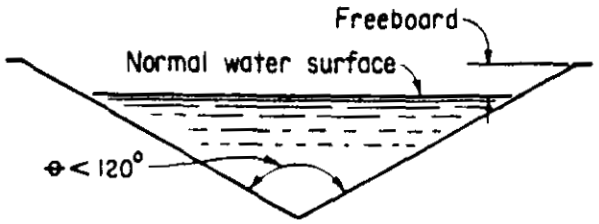

Figure 2-44. **Theoretical waveless chute section. Triangular shape prevents both cross waves and slug flow. 103-D-1278**

surging flow that does occur. Possible design changes include:

(1) Divide the flow in the chute section with a wall down the center of the chute.

(2) Change the shape of the section. The theoretical waveless shapes could be considered.

(3) Reduce the length of the chute. A series of shorter chutes or drops could be considered.

(4) Steepen the chute.

(5) Replace the open channel chute section with pipe.

If these design changes are impractical, the chute section might be adapted to accommodate surging flow by:

(1) Increasing the freeboard of the chute walls.

(2) Providing a cover for the chute section to contain the waves, or

(3) Protecting the backfill around the chute section with riprap or paving.

Adaptations to the stilling pool could include:

(1) Designing the pool to provide for the momentary surge discharge. This would

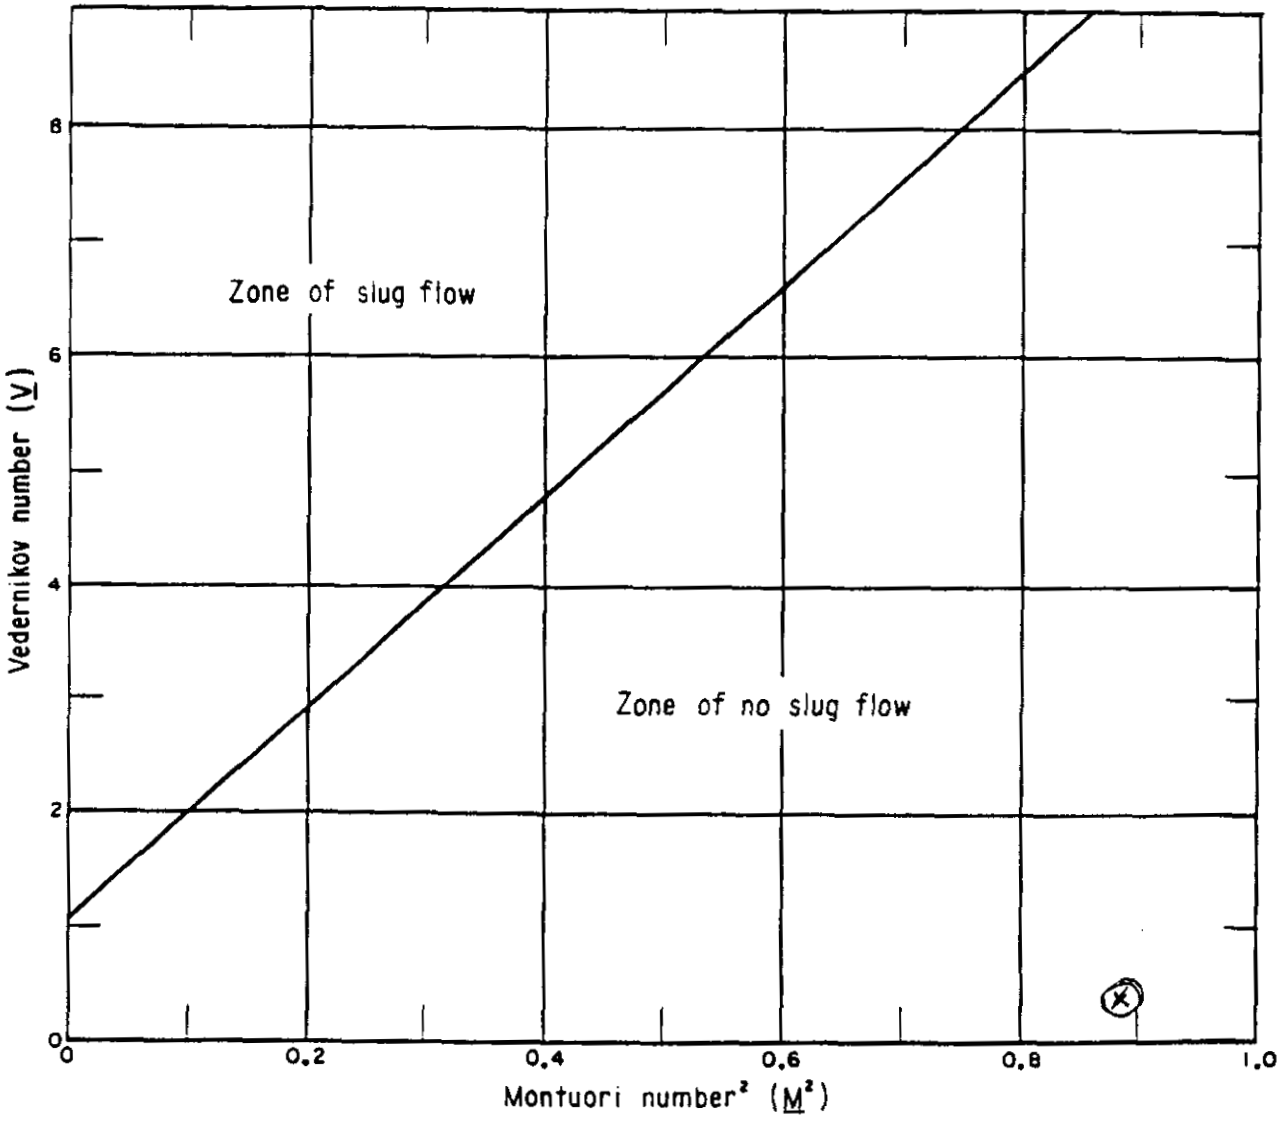

Figure 2-45. Criteria for slug flow. 103-D-1279

provide a longer pool and higher pool walls to contain the surge.

(2) Provide additional riprap to protect the channel downstream and the backfill around the pool.

(3) Provide a surge suppressing device in the stilling pool. A baffle or weir wall in the pool could prevent flow from sweeping through the pool and outlet transition (fig. 2-48). Weir walls could also provide tailwater to submerge the surges. Rafts or other floating wave dampeners could be used.

(4) An energy dissipator less sensitive to surging could be used.

The study of wave action in chute structures is based largely on empirical data. If a serious wave problem in a structure is indicated, further studies should be undertaken to verify the extent of the problem and the effectiveness of the proposed solutions.

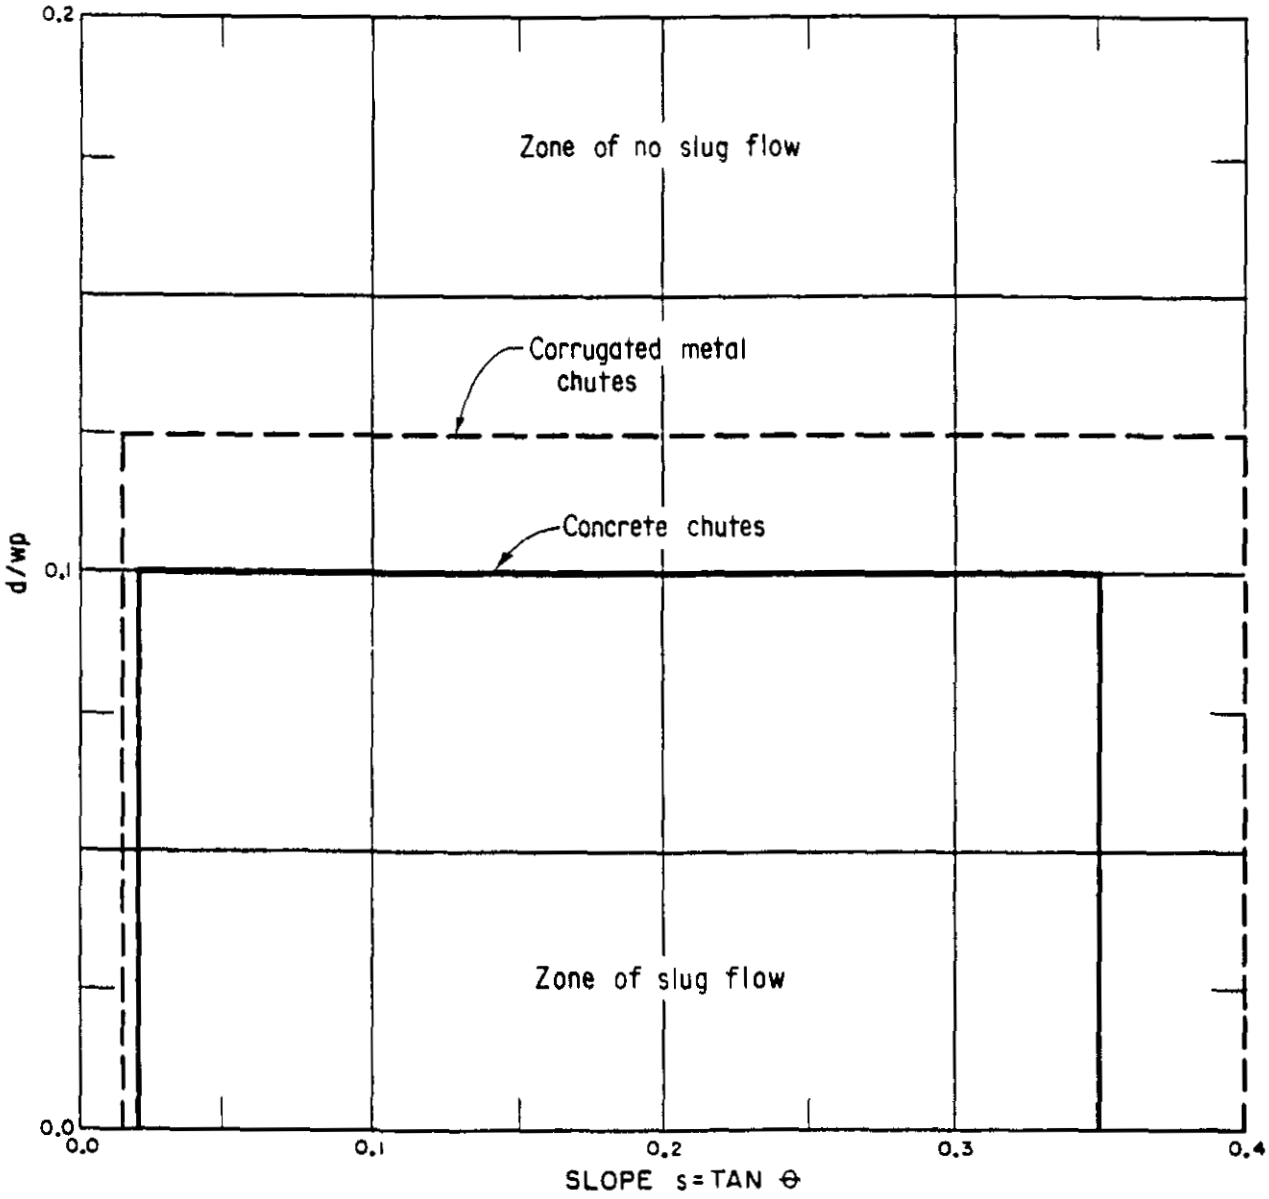

Figure 2-46. **Shape and slope criteria for slug flow. 103-D-1280**

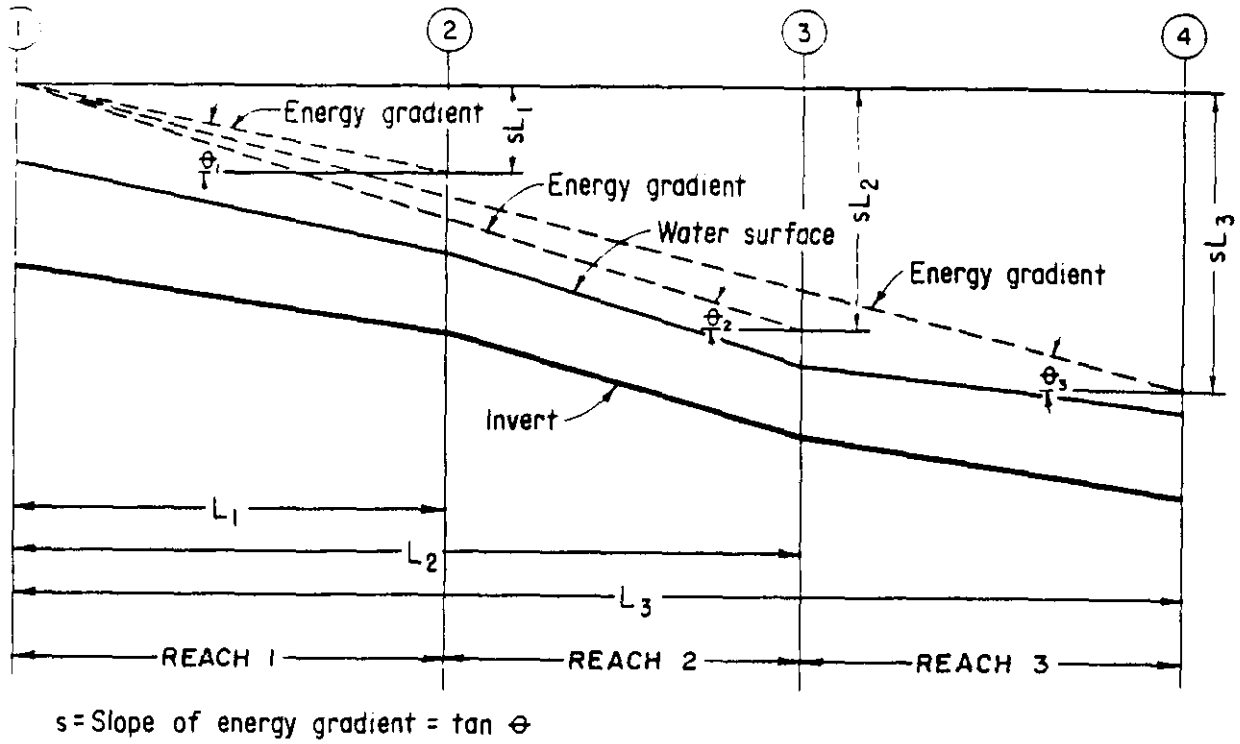

Figure 2-47. **Invert, water surface, and energy profiles of a chute structure. 103-D-1281**

2-35. *Design Procedure.*–

(1) Select and design the type of inlet to be used.

(2) Determine the energy gradient at the beginning of the chute section.

Figure 2-48. **Wave sweeping through the outlet transition of a stilling pool. Flow is 140 cfs. P222-117-36227**

(3) Compute the variables of flow down the chute section.

(4) Design the trajectory and the steep portion of the chute section.

(5) Assume an elevation for the floor of the stilling pool and compute the characteristics of flow upstream of the hydraulic jump.

Determine d_2 and the energy gradient after the hydraulic jump.

(6) Determine the energy gradient in the channel downstream and compare to the energy gradient after the jump.

(7) It may be necessary to assume a new pool invert elevation and to recompute the above values several times before a check in energy gradients is obtained.

(8) Review for proper operation at partial capacity.

(9) Determine the length of the pool and the height of the pool walls.

(10) Design the chute and floor blocks and the end sill or outlet transition as required.

(11) Check the possibility of waves developing on the structure.

EXECUTIVE SUMMARY

INTRODUCTION

Boyle Engineering Corporation was authorized to evaluate and develop preliminary designs of drainage facilities within the Eastern and Western Tributaries of Range Wash by an agreement between Boyle Engineering Corporation and the City of North Las Vegas dated January 18, 1989.

STUDY AREA DESCRIPTION

The Range Wash drainage basin is located in the northeast portion of the Las Vegas Valley. It is bounded on the north and east by the Las Vegas Mountain Range and on the west by the Las Vegas Wash basin. The Range Wash basin outfalls into Las Vegas Wash adjacent to the Sunrise Station Power Plant. The mainstem of Range Wash extends north along Sloan Channel to the southern limit of Nellis Air Force Base at the confluence of the Western and Eastern Tributaries. The western tributary extends to the northwest into the Las Vegas Mountain Range. The eastern tributary extends northeasterly into the Las Vegas Dunes Recreation Lands.

The basin is characterized by three distinct land types; mountainous; alluvial fan, and; urban developed. The mountainous regions are steep with limited vegetation and high runoff potential. The alluvial fan has relatively low runoff potential, however the existence of numerous incised channels makes hydrologic response difficult to predict. The area downstream of I-15 is generally highly developed with quick, high intensity runoff due to the large amount of impervious surface.

HYDROLOGIC EVALUATION

A hydrologic evaluation of the Range Wash basin was performed as part of this study. The U.S. Army Corps of Engineers' HEC-1 computed probability simulation was the basis for this study. Clark County Regional Flood Control District rainfall amounts and distributions were used to determine design storms, SCS curve numbers simulated rainfall abstractions, and runoff was generated using the SCS dimensionless unit hydrograph or the Kinematic wave overland flow

plane methodology of HEC-1. Channel routing was accomplished through the use of Kinematic Wave or Muskingum routing. Once developed, the model was calibrated to match the regionally calibrated Corps of Engineers computed probability discharge estimates. The results of the hydrologic analysis are summarized in the following table.

HYDROLOGIC SUMMARY
FUTURE BASIN DEVELOPMENT

Location	100-Year Event Peak Flow (cfs)	100-Year Event Runoff Volume (acre-ft)
Western Tributary at Confluence	7260	2180
Eastern Tributary at Confluence	3370	1040
Range Wash at Las Vegas Wash	8870	3300

Subsequent to the completion of the hydrologic modelling, CCRFCD adopted new hydrologic criteria. Since this model was calibrated to computed probability discharges, a change in methodology should not result in significantly different discharges. CCRFCD also initiated a concurrent Master Plan Update. That study also resulted in discharges similar to those presented in this study.

CONCEPTUAL ALTERNATIVE DEVELOPMENT

Four alternatives were identified which reduced flood hazard to existing structures, which minimized exposure of possible future developments to flooding and which satisfied FEMA requirements. The four alternatives were:

I) The Master Plan alternative. This is the alternative proposed in the existing Master Plan with some minor adjustment of facility locations to reflect projected development.

II) The Beltway diversion alternative. This involves an alluvial fan apex detention facility, diversion of fan flows via the projected beltway alignment, a detention basin at the I-15

crossing of the West Tributary and detention at the confluence of the East and West Tributaries of Range Wash. Detention facilities will be sized to limit flows to existing channel capacities, if possible.

III) The Master Plan with confluence detention alternative. This includes the Master Plan alternative with additional detention at the confluence to minimize or eliminate the necessity of improvements to the Sloan Channel.

IV) The North Las Vegas Detention Basin Diversion alternative. This is generally alternative III with Western Tributary storage eliminated and replaced with a diversion to the North Las Vegas Detention Basin.

Conceptual costs of each alternative were estimated and are summarized in the following table.

SUMMARY OF CONCEPTUAL FACILITY COSTS
(Millions of Dollars)

Alternative		East Tributary	West Tributary	Sloan Channel	Total
I	Facility	$ 12.0	$ 29.0	$ 9.3	
	Land	2.2	2.3	0.0	
	Contingency	2.8	6.2	1.9	
	Total	$ 17.0	$ 38.0	$ 11.0	$ 66.0
II	Facility	$ 30.0	$ 10.0	$ 6.9	
	Land	1.5	1.1	1.0	
	Contingency	6.3	2.3	1.6	
	Total	$ 38.0	$ 13.0	$ 9.5	$ 61.0
III	Facility	$ 12.0	$ 29.0	$ 6.9	
	Land	2.2	2.3	0.8	
	Contingency	2.8	6.2	1.5	
	Total	$ 17.0	$ 38.0	$ 9.2	$ 64.0
IV	Facility	$ 12.0	$ 17.0	$ 6.9	
	Land	2.2	0.9	0.8	
	Contingency	2.8	3.6	1.5	
	Total	$ 17.0	$ 22.0	$ 9.2	$ 48.0

All evaluated alternatives reduce the hazard of flooding as a result of detention and improved conveyance. Alternative I is the most costly due to the expense of improving Sloan Channel to convey design discharges. Alternative III is essentially the same as Alternative I, except that it substitutes the confluence detention basin for improvements along Sloan Channel. Alternative II relies on the proposed Beltway and provides minimal protection to facilities on the fan to the north. Alternative IV is significantly less expensive than the other alternatives, however it relies on an interbasin diversion, which may increase hazard or the perceived hazard in the receiving watershed.

Subsequent to review, Alternatives III and IV were selected for further evaluation and preliminary design. The selection of the alternatives was based largely on estimated construction cost and as a result of the uncertainty of the alignment of the proposed beltway.

PRELIMINARY DESIGN

The purpose of the preliminary design is to identify general components of the selected alternatives such as types and sizes of facilities and their approximate location. The sizing of facilities is based on a refinement of the hydrologic model and hydraulic analysis. Design of detention facilities includes estimates of required storage volume, embankment height and spillway geometry. Channel and floodway design includes slope, geometry and lining type. Street crossings include identification of required culvert sizes or bridge spans. Preliminary horizontal alignments of channel and crossing facilities are identified schematically on the drawings developed. Vertical elevations are identified using the available topographic information. Utilizing the alignments and grades established by this design, utility conflicts are identified and reconciled to the extent possible. Right-of-way acquisition limits are estimated and included. The previously prepared cost estimates are refined to reflect the preliminary design effort.

The preliminary designs for Alternative III and Alternative IV are depicted on the drawings presented as Appendix A of the report. This preliminary design is conceptual in nature and lacks significant detail because no detailed topography was developed for this study. Utility owners were notified and utility maps made available were consolidated during the study. The utilities identified on the plans are those reported by the various utility owners. This information was used during the conceptual evaluation and the preliminary design to reconcile potential utility conflicts. The horizontal alignments depicted on the plans are related to physical features identified through field observation and from the available mapping. The alignments are

generally identified by their relation to existing facilities such as road crossings or channels or by their proximity to existing rights-of-way. Vertical alignments are based on the 20-foot contour interval presented on the USGS quadrangle maps.

Opinions of probable cost were estimated for each alternative and are summarized in the following table. The cost estimates prepared during this study reflect the preliminary nature of the project. No detailed structural analysis or design was performed for the facilities nor was a detailed estimate of earthwork prepared. The costs represent estimates consistent with the level of detail of the study and the topographic mapping available. Appropriate contingencies have been included in the cost estimates to reflect the lack of detail of the available information.

SUMMARY OF PRELIMINARY FACILITY COSTS
(Millions of Dollars)

Alternative		East Tributary	West Tributary	Sloan Channel	Total
III	Facility	$ 11.6	$ 24.8	$ 8.6	
	Land	1.2	3.2	1.9	
	Contingency	2.6	5.6	2.1	
	Total	$ 15.4	$ 33.6	$ 12.6	$ 61.6
IV	Facility	$ 11.6	$ 10.6	$ 8.6	
	Land	1.2	1.2	1.9	
	Contingency	2.6	2.4	2.1	
	Total	$ 15.4	$ 14.2	$ 12.6	$ 42.2

RECOMMENDED PLAN

The City of North Las Vegas and the Clark County Regional Flood Control District have selected Alternative IV as their preferred alternative. This alternative features the diversion of western tributary flows to the existing North Las Vegas detention basin. It also includes conveyance downstream of Interstate 15 on the western tributary and detention and conveyance along the eastern tributary from the fan downstream to the confluence with the western tributary. Detention is proposed at the confluence and limited channel improvements are required downstream before discharging into the Las Vegas Wash.

This plan utilizes existing facilities to the greatest extent practicable by limiting flow rates to existing capacities or adding facilities to inadequate existing structures. New facilities are proposed where no existing facilities are in place or where existing facilities are not compatible with proposed ones. By adopting this approach, the desired flood protection is provided at lower cost.

Because sufficient funds are not available to construct all the facilities identified in this plan, an implementation plan has been formulated. The plan weighs the need for the improvements along with the cost and relative benefit to develop a priority list. Using the criteria, two facilities are of highest priority; the Western tributary diversion dike and the confluence detention basin.

The importance of the western tributary dike and the resulting flow reduction has long been recognized. The existing Master Plan identifies a detention basin which achieves the same objective as does dike construction. This facility was funded in the District's 10-year program. Since the dike serves the same function, at lower cost, its priority is clear. The timeliness of this is even more evident given the ongoing development pressures which exist on this portion of the fan.

Past flooding, and the highest degree of residential development, have occurred along the Sloan Channel. To most cost effectively reduce the flooding and subsequent damage, the confluence detention basin should be constructed. To collect and convey Western Tributary flows, the golf course channel must be constructed concurrently.

The following table presents a recommended priority listing of the facilities identified in this plan.

IMPLEMENTATION PRIORITY

Priority	Facility Description	Facility Designation
1A	Western Tributary Diversion Dike	Dike W-1
1B	Confluence Detention Basin and Golf Course Channel	Basin R-M and Channel W-9D
2	Property Acquisition for East Tributary Detention Basin	Basin E-J1 land
3	Sloan Channel Improvements	Channels R-1 to R-7
4	West Tributary Channel from from UPRR to Golf Course Channel	Channels W-6 to W-9
5	East Tributary Detention Basin and Channel to Forrestal	Basin E-J1 and Channels B-4 and E-5
6	East Tributary Channel and dikes upstream of Detention Basin	Dike E-1A and Floodway E-2A
7	East Tributary Channel Forrestal to Confluence Detention Basin	Channels E-6 and E-7

I - INTRODUCTION

GENERAL INTRODUCTION

The evaluation and preliminary design of drainage facilities within the Eastern and Western Tributaries of Range Wash upstream of the Sloan Channel, in the Las Vegas Valley area of Nevada, was performed under the terms of an agreement executed on January 18, 1989 between the City of North Las Vegas, Nevada and Boyle Engineering Corporation.

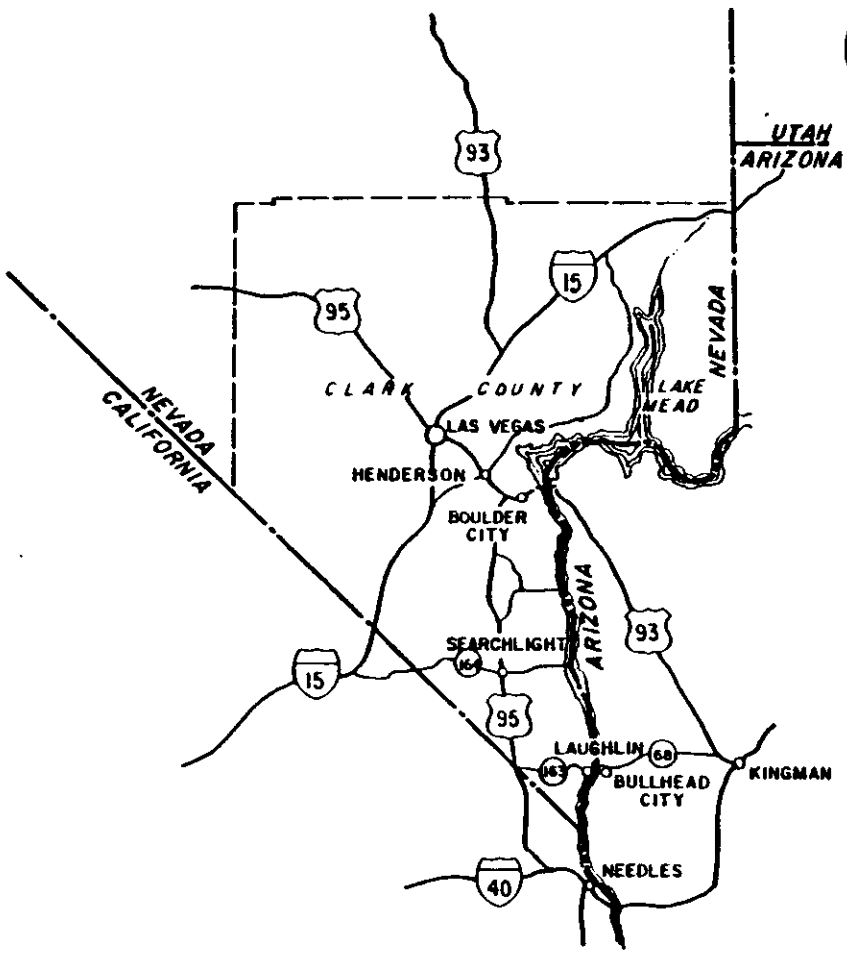
The purpose of the project is to evaluate and develop preliminary designs for drainage facilities within the Eastern and Western Tributaries of Range Wash. The effort includes a review of previously developed studies, updating and refining existing hydrologic models, development and evaluation of alternative flood control facilities, conceptual design of selected flood control facilities within the Western and Eastern Tributaries of Range Wash, and the preparation of a report summarizing the effort.

PROJECT LOCATION

The Range Wash drainage basin is located in the northeast portion of the Las Vegas Valley (Figure I-1). The study area boundary is bounded on the north and east by the Las Vegas Mountain Range and extends into the Desert National Wildlife Range.

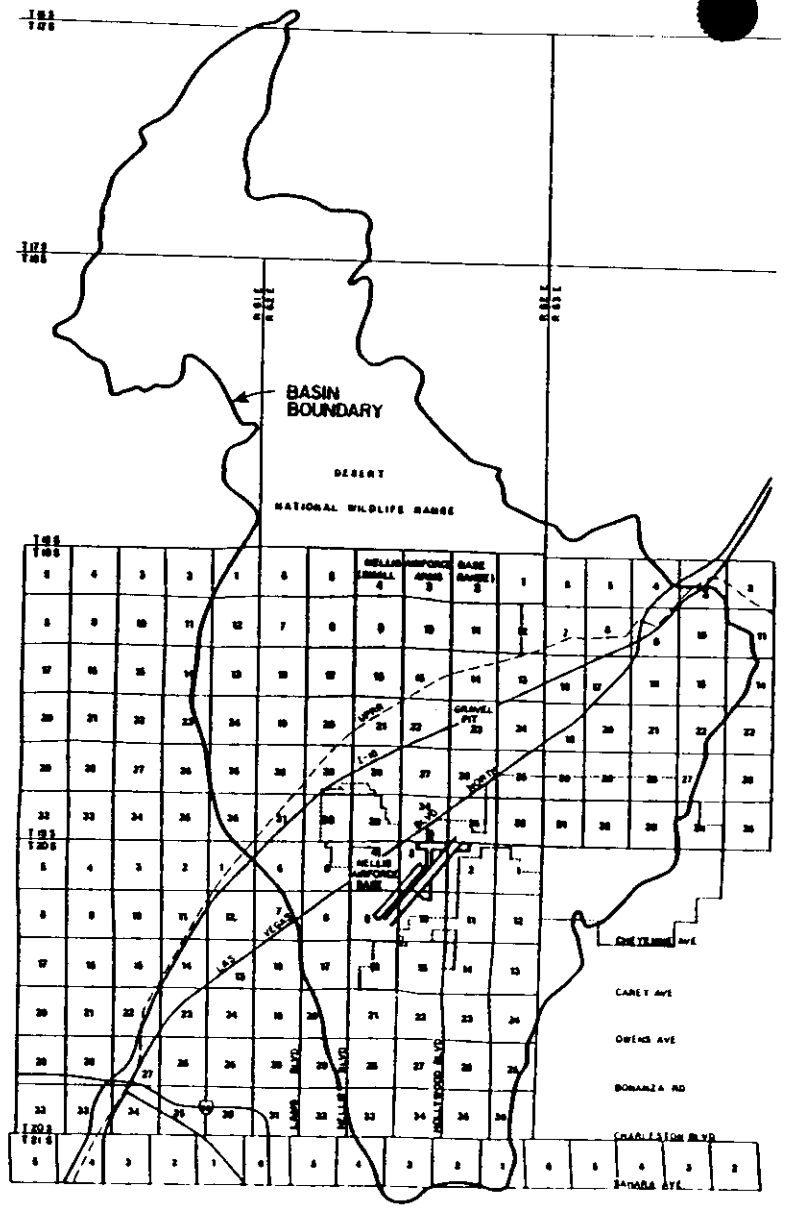
The basin lies entirely within Clark County, Nevada and includes portions of the City of North Las Vegas, Nellis Air Force Base, and portions of unincorporated Clark County. The entire drainage area is contained within the boundaries of the Clark County Regional Flood Control District.

The Range Wash Drainage Basin is a tributary to Las Vegas Wash. Flows from Range Wash enter Las Vegas Wash adjacent to the Sunrise Station Power Plant near the intersection of Vegas Valley Drive and Hollywood Boulevard. The mainstem of Range Wash extends north from this location approximately five miles along the Sloan Channel to the southern limit of Nellis Air Force Base, at the confluence of the Western Tributary of Range Wash with the Eastern Tributary of Range Wash.



LOCATION MAP

NOT TO SCALE



VICINITY MAP

NOT TO SCALE

FIGURE I-1

From the confluence the Western Tributary of Range Wash extends along the western boundary of Nellis Air Force Base, then northwesterly to I-15, crossing Las Vegas Boulevard North, Lamb Boulevard, and Craig Road. Upstream of I-15 and the Union Pacific Railroad, the channel is poorly defined with numerous minor channels distributed across the alluvial fan. Upstream of the alluvial fan area, in the Las Vegas Mountain Range, channels are well defined.

The Eastern Tributary of Range Wash extends from the confluence around the eastern boundary of Nellis Air Force to a point near the intersection of O'Bannon Road and Forrestal Boulevard. Here, two fairly distinct branches join. The easterly branch extends northeasterly into the Las Vegas Dunes Recreation Lands area. The westerly branch collects flows from an area to the north and east of the Western Tributary alluvial fan.

The basin can be characterized by three distinct land types: mountainous; alluvial fan, and; urban developed. The mountainous regions of the watershed are steep, rocky areas with limited vegetation and high runoff potential. Areas on the alluvial fan are characterized by alluvial deposits and numerous incised channels of limited capacity. Runoff from this area is relatively low and hydraulic conditions are such that the route of flood flows is difficult to predict. The highly developed area, downstream of I-15, is generally characterized by existing residential and commercial developments and Nellis Air Force Base, with rapid development and construction of additional commercial and residential developments. Runoff from this area is rapid and high due to the large amount of impervious surface found in the area.

PROJECT SCOPE

The purpose for the drainage planning study for the Western and Eastern Tributaries of Range Wash is to develop a planning document to direct the design and construction of drainage improvements within the watershed. Using this document, priorities and budgets for improvements can be established, possible future problems can be averted and land development can proceed with a better understanding of the flood hazards and the required mitigation measures.

The drainage planning study for the Western and Eastern Tributaries of Range Wash involves the preparation of conceptual designs for drainage improvements along the two tributaries of Range Wash. The defined scope of work includes the five following principal components:

- o Data Collection and Project Coordination;
- o Hydrologic Analysis;
- o Alternative Development and Evaluation;
- o Conceptual Design of Drainage Improvements, and;
- o Report Preparation

Data collection and project coordination were among the first tasks performed for the project and continued throughout the duration of the project. This effort involved obtaining and reviewing past hydrologic studies of the watershed, alternative flood control measures previously proposed within the watershed, and record drawings of existing storm drainage facilities. The effort also included the collection and review of utility plans, land-use plans and the identification of regulatory requirements imposed on potential improvements within the watershed. An initial meeting and on-going project coordination meetings were held to facilitate the collection of data, to review project progress, and to discuss project results. These meetings included representatives from the City of North Las Vegas, the Clark County Regional Flood Control District, Clark County Public Works Department, Nellis Air Force Base, and the Cities of Henderson and Las Vegas. In addition to those in attendance at the meetings, coordination and communication with other agencies such as the Federal Emergency Management Agency and the U.S. Army Corps of Engineers was also established and maintained throughout the project duration.

A hydrologic analysis was performed for the Range Wash watershed. This analysis included an evaluation of the hydrologic response of the Western and Eastern Tributaries of Range Wash for both the existing and future drainage basin conditions. A hydrologic computer model was utilized to simulate the response of the watershed to design rain storms. The model was calibrated to the computed probability results presented by the U.S. Army Corps of Engineers in their Feasibility Study. A sediment yield analysis was also performed to estimate probable sediment volumes reaching the proposed facilities.

The results of the hydrologic analysis were used to identify problem areas and establish design discharges for proposed facilities within the watershed. The model was also used to refine the sizing of selected facilities, to evaluate the impacts of selected facilities on downstream facilities and to estimate design flow rates for the selected facilities.

The development and evaluation of alternative flood control facilities which address the identified problems within the watershed was a two step process. The first step was the development and evaluation of conceptual alternatives at a level of detail sufficient to establish general facility type and size. The second step was a conceptual analysis and provided additional information regarding facility alignment, size and type.

Four conceptual alternative facilities were identified for the control of flooding within the Range Wash watershed. These facilities were developed in coordination with the City of North Las Vegas, the Clark County Regional Flood Control District, and the other agencies identified and involved in the project. These alternatives were selected to reconcile the identified technical, economic, political and aesthetic considerations within the watershed.

The evaluation of the four conceptual alternatives included locating, sizing and cost estimating the various component facilities. Because of the conceptual nature of this analysis simplifying assumptions were made to identify the most attractive alternatives for further study. These assumptions include the use of simplified hydrologic techniques, consistent with the conceptual level of analysis, to size facilities and evaluate their impacts. Normal flow assumptions are used for the sizing of channels, pipes and culverts and alignments in general corridors, rather in specific locations, are considered. The conceptual evaluation established relative facility locations, sizes and costs and, in conjunction with other nontechnical considerations, allowed for the selection of certain alternatives for further evaluation.

Two of the four conceptual alternatives were selected for further refinement. This refinement effort included a more detailed hydrologic impact assessment, more site-specific facility sizing, more extensive hydraulic analysis, more detailed cost estimate preparation and the preparation of conceptual designs. The conceptual design included sizing of hydraulic structures including bridge and street crossings, a determination of the hydraulic grade line through the proposed facilities, and a determination of a conceptual vertical alignment of the proposed facilities. Facilities sized and located in this conceptual design process were included in the detailed hydrologic model to assess their impacts on the overall system. Modifications and refinements to facilities were made as a result of the detailed modelling.

In addition to the conceptual design of the facilities, estimates of probable right-of-way requirements for the alternatives were included. This information, along with the general details of the conceptual design, are presented on plan and profile sheets.

This report summarizes the analysis and evaluations performed for the project. A discussion of the approach, results and conclusions is included along with a brief discussion of the alternatives, and a presentation of the conceptual design plan and profile drawings. Included in the report is a phasing plan to facilitate the implementation of the Plan.

EXISTING DATA

Data from several sources was collected which might effect the feasibility and economics of the various alternative facilities. Sources for the data included governmental agencies such as the City of North Las Vegas, Clark County Public Works Department, Clark County Regional Flood Control District, and Clark County Comprehensive Planning. Other governmental agencies were contacted to identify and collect additional information. These agencies included Nellis Air Force Base, the Federal Emergency Management Agency, and the U.S. Army Corps of Engineers. Utility information was also collected from the various utility companies within the watershed including the Clark County Sanitation District, Nevada Power Company, Southwest Gas Corporation, and telephone and cable TV companies. The information obtained from the various sources was important in identifying the extent of existing facilities within the watershed. Existing drainage improvements were also identified. These included existing channels, street crossings and existing detention facilities which might be utilized for alternative plans.

Land uses within the watershed were perhaps the most important constraint to proposed facilities. Land-use information identified both the character and type of existing development, as well as proposed development locations and extent. Existing land uses within the watershed were identified using combinations of available mapping, area photographs, and field reconnaissance. This information was supplemented by existing hydrologic and planning studies available for the basin. Future land-use information was obtained from the City of North Las Vegas Land-Use Plan, Clark County Comprehensive Planning, and the previous studies. This information was compiled and presented to the City of North Las Vegas and the other interested agencies for review and comment. Subsequent to the initial collection effort, the City of North Las Vegas provided amended land-use plans which resulted in a slight modification of development limits and facility sites. This information was utilized to identify feasible alignments and facility sites.

EXISTING BASIN DESCRIPTION

The Range Wash drainage basin is located in the northeast portion of the Las Vegas Valley. The watershed drains a western tributary and an eastern tributary. The Range Wash basin is tributary to Las Vegas Wash with its outfall near the Sunrise Station Power Plant. Flow in the basin is generally from north to south. The Western Tributary watershed headwaters are in the uplands of the Las Vegas Mountain Range. Runoff leaving the Las Vegas Mountain Range flows across an alluvial fan in a southerly direction and is intercepted by a Union Pacific Railroad line and Interstate 15. After crossing these roads, flow is in a general southeasterly direction to the southern portion of Nellis Air Force Base where it joins flows from the Eastern Tributary. Eastern tributary flows begin in the lower portions of the Las Vegas Mountain Range in the Las Vegas Dunes Recreational Lands area just to the northeast of the intersection of Interstate 15 with Las Vegas Boulevard north. Flow from this area is generally to the south or southwest and passes along the eastern border of the Nellis Air Force Base main base area. Here flows combine and flow in a southwesterly direction to the southern portion of Nellis Air Force Base where they join with Western Tributary flows. Combined flows then proceed southward along the Sloan Channel to the ultimate outfall into Las Vegas Wash.

The watershed consists of three distinct regions: the northern and eastern mountainous areas; the central alluvial fan, and; the downstream developed basin. The mountainous areas are rugged and steep with nominal vegetation and high runoff potential. The alluvial fan area is characterized by numerous small incised channels across the steep alluvial fan areas. The downstream developed areas of the watershed are combinations of residential and commercial developments.

At the transition from the alluvial fan areas to the downstream developed areas lies Nellis Air Force Base. This property is affected by flows from both the Western Tributary and the Eastern Tributary of Range Wash. Nellis is somewhat protected by the presence of Interstate 15, the Union Pacific Railroad, and Las Vegas Boulevard North. Crossings of these streets or railroads concentrate flows and subject the Air Force Base to concentrated flows.

Existing drainage facilities within the Range Wash basin are relatively limited. Sloan Channel improvements are designed and partially constructed. This affords some limited protection to downstream properties. The Vandenberg Channel, immediately downstream of I-15, is another improved section of the channel. Nellis Air Force Base has completed improvements to several segments of the channel in and around the Air Force Base for the protection of Air Force property. Beyond these channel structures, the improvements are generally limited to street

and railroad crossing structures which are frequently inadequate to convey the full 100-year flows. The Clark County Regional Flood Control District Master Plan has identified several facilities to control runoff from the Western and Eastern tributaries of Range Wash. These facilities are incorporated into the alternatives evaluated. The facilities proposed in the Regional Flood Control District Master Plan have not been designed or constructed.

Chapter 1

Hydrol...

II - HYDROLOGY

INTRODUCTION

Hydrologic analyses were performed for the Western and Eastern Tributaries of Range Wash upstream of Las Vegas Wash. The purpose of these analyses was to update past hydrologic studies and to develop detailed hydrology for the evaluation and of sizing facilities in the Range Wash watershed.

The Clark County Regional Flood Control District Master Plan developed hydrology for the entire Clark County area including Range Wash. This effort, while comprehensive in scope, was predicated on a number of generalized regional assumptions. These assumptions render the flows developed for individual watersheds inadequate when evaluating site specific facilities.

The U.S. Army Corps of Engineers developed a computer model for the Las Vegas Valley which was based on the Master Plan model. This model refined some of the regional assumptions used in the Master Plan and is more useful in evaluating site specific facilities. The Corp of Engineers model did not provide a sufficient level of discretization, nor did it utilize sufficient detail in representing rainfall losses, to be used without modification in this study.

The following sections present Boyle's approach in the development of a hydrologic model for the Western and Eastern Tributaries of Range Wash including methodologies, assumptions and results of the analyses. The adopted methodologies are based on the Hydrologic Memorandum submitted on March 27, 1989.

MODELING APPROACH

The hydrologic model utilized was the Flood Hydrograph Package (HEC-1) developed by the U.S. Army Corps of Engineers, Hydrologic Engineering Center. HEC-1 is a rainfall-runoff event simulation model which uses an interconnected system of hydrologic and hydraulic components to simulate the surface runoff response of a drainage area to precipitation. This package has been used in many previous studies in the Las Vegas Valley, including the Master Plan and the Corps of Engineers Feasibility Study.

The Clark County Regional Flood Control District (CCRFCD) procedure for determining rainfall amounts and distributions was used to develop estimates for the 10-, 25-, 50- and 100-year storms. Hydrometerological Report No. 49 (HMR-49) was used to develop the estimated rainfall for the probable maximum precipitation (PMP) event.

The USDA Soil Conservation Service (SCS) curve number methodology was used to estimate loss rates because it provides a deterministic method based on soil type and cover. The SCS dimensionless unit hydrograph methodology was used to develop runoff hydrographs for predominantly undeveloped subbasins north of Interstate 15 and east of the developed metropolitan area. The kinematic wave overland flow plane methodology was used to generate hydrographs for developed subbasins.

Kinematic wave flood routing was used to route flow along channel segments having well defined channels. The Muskingum method was used for routing flows across alluvial fans and in subbasins with poorly defined or undersized channels. Little attenuation is expected when using the kinematic wave method which is consistent with flow through well defined, adequately sized channels. In other channel reaches, overbank storage effects are considerable and can best be accounted for through use of the Muskingum method.

The model was then calibrated by adjusting the curve numbers through modification of the Antecedent Moisture Condition assumptions until the regionally-calibrated Corps of Engineers computed probability discharge estimates were achieved.

Subsequent to the completion of the hydrologic modelling, CCRFCD adopted new criteria which revised some of the basic information used as input into hydrologic models. The most significant revision affecting this study was the adoption of a revised areal reduction relationship. Because the results of the hydrologic modelling effort under taken for this project are calibrated to the Corps of Engineers' computed discharges, and because future modelling efforts will generally be required to yield similar results, no attempt was made to revise the model.

A concurrent project for the CCRFCD to update the Las Vegas Valley Master Plan also included a hydrologic modelling effort. As expected, that study yielded results similar to those presented in this report. Some differences in basin routing were identified in that study, however no changes in the identified facilities or facility sizes result from those differences.

BASIN CHARACTERISTICS

Subbasin Delineation

The watershed was delineated and subdivided into 38 separate subbasins ranging in area from approximately one-half to ten square miles. The subbasin locations are presented in Figure II-1. Individual subbasin areas, in addition to other information, have been tabulated in Table II-3. Subbasin boundaries and their designation are generally based upon delineations and names used by the Corps of Engineers (COE) Feasibility Study and the CCRFCD Master Plan. Boundaries were adjusted and new subbasins added to provide a more detailed simulation of watershed response.

Hydrologic points of interest (nodes) such as confluences, possible structure locations and outfall points were identified. A schematic diagram of the subbasins, nodes and routing links is presented in Figure II-2.

Precipitation

Point precipitation values were obtained for the 10-, 25-, 50-, and 100-year recurrence interval storms using the NOAA Atlas 2, "Precipitation - Frequency Atlas of the Western United States, Volume VII - Nevada", (NOAA Atlas) as presented in the Draft Rainfall for the Clark County Regional Flood Control District Area manual (Draft CCRFCD manual). Table II-1 lists the NOAA point precipitation values for each recurrence interval storm by subbasin.

In accordance with procedures outlined in the Draft CCRFCD Manual, point precipitation values were modified to account for rainfall records not available at the time of NOAA Atlas publication. The COE, Los Angeles District (LACOE) developed ratio adjustments for various recurrence intervals which were used to modify the NOAA values to arrive at the point rainfall values used as the basis for model simulation precipitation. The ratios are listed in Table II-2.

Temporal and Areal Rainfall Distribution

The 6-hour design storm duration was chosen for modeling purposes. This storm duration represents the local storm generally accepted for detention facility sizing and, because of the rainfall distribution, also results in acceptable peak flow estimates.

Five different storm distributions, each assigned a Storm Distribution Number (SDN), have been developed by the LACOE. The appropriate SDN was utilized based on the size of the contributing drainage area and storm recurrence interval. SDN 5, the least intense distribution, was used for all analyses since even the partial basin simulations included a drainage area consistent with the SDN 5 distribution assumption.

The rainfall depths listed in Table II-1 represent NOAA point rainfall values. The NOAA point rainfall values were increased to reflect the Table II-2 ratios and further adjusted to areal rainfall values using Depth Area Reduction Factors (DARF) from the CCRFCD manual for each specific storm areal extent and location.

Several rainstorms were evaluated to estimate peak flows from storms of different areal extent located over different portions of the basin. The DARF was adjusted to reflect tributary subbasins and only appropriate sub-basins were modeled in each storm simulation. To represent a rainstorm over the entire basin, "Total Basin Storm", a DARF equal to 0.62 was used

to reduce the point precipitation values over all subbasins. This storm also was used to simulate peak flows at the confluence of the Eastern and Western tributaries.

The "Upland Storm" simulation represents a rainstorm over the upland part of the basin which is tributary to the proposed detention facility sites identified in the Master Plan for each tributary. This consists of the currently undeveloped portion of the basin. This area is also above the probable development limits and is expected to remain largely undeveloped due to the mountainous terrain. A DARF of 0.72 was used in the simulation to adjust rainfall in each tributary above the identified detention basin sites.

The "Tributary Basin Storm" represents a storm located over each tributary. A DARF of 0.68 was used for this simulation and represents rainfall over each tributary basin individually. This storm is intended to represent the maximum flows in each tributary and can be used to determine the temporal distribution of runoff from each tributary.

The final storm "Lower Basin Storm" represents a rainstorm over the lower portion of the basin. This area is subject to intense development and potentially high unit runoff. For this simulation, it was assumed that no rainfall occurs in the upper portion of the basin and that the lower watershed is the only contributor of runoff. A DARF of 0.69 was used to simulate this storm.

Figure II-3 presents the coverage of the various storms in a schematic manner.

Probable Maximum Precipitation

The probable maximum precipitation estimate was determined using HMR-49, titled "Probable Maximum Precipitation Estimates, Colorado River and Great Basin Drainages", prepared by the U.S. Department of Commerce and the U.S. Department of Army, reprinted in 1984. The local storm procedure was used to develop the amounts and distribution for the 6-hour probable maximum precipitation (PMP) for both 40 square-mile basins above the two identified detention facility sites. The 6-hour precipitation of 10.35 inches was applied to each subbasin in the probable maximum flood (PMF) analysis.

SUBBASIN INPUT PARAMETERS

Curve Numbers and Loss Rates

Vegetative interception, depression storage, and infiltration are collectively referred to in the HEC-1 model as precipitation losses. The SCS curve number method was selected for use in

RANGE WASH
STORM SCHEMATIC

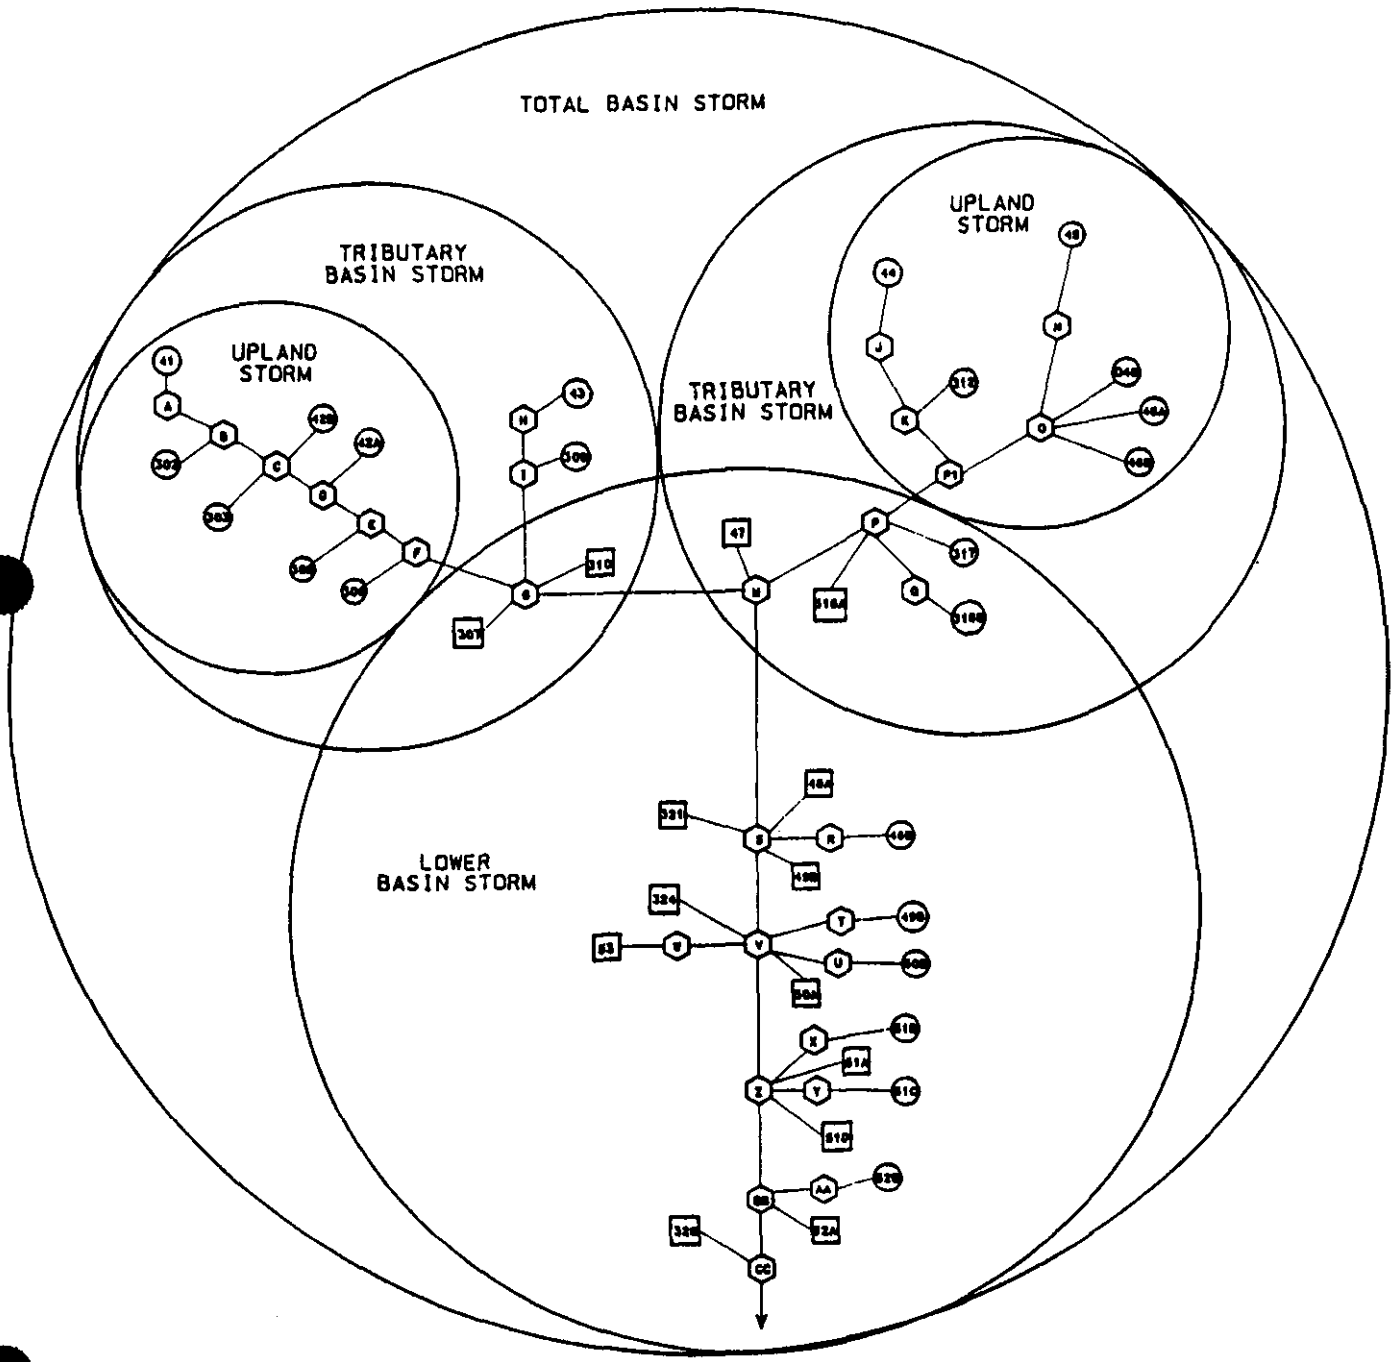

FIGURE II-3

estimating those losses. In this method, losses are related to the drainage characteristics of the soil and the land cover using the curve number, and are a function of the rainfall depth at each time step. Curve numbers were assigned to each subbasin based upon their predominant soil type, land use, type and quality of vegetation, and degree of development. The hydrologic soils group for the soils within the watershed are depicted on Figure II-4. These curve numbers represent runoff conditions assuming antecedent moisture condition (AMC) 2, the average condition. AMC 2 curve numbers for each subbasin are presented, along with other parameters, in Table II-3.

For subbasins modeled using the SCS Unit Hydrograph procedure, AMC 2 curve numbers were assigned using hydrologic soil group and cover information provided by Clark County SCS personnel. Composite subbasin curve numbers were developed using a weighted average of individual curve numbers representing different soil types and covers. It was assumed that vegetative cover was "open brush" in fair to poor condition for all undeveloped subbasins which were modeled using this procedure. The resulting curve numbers are consistent with other common cover types such as desert shrub.

Curve numbers (AMC 2) for developed areas were assigned using guidelines in "Urban Hydrology for Small Watersheds" (TR-55) by the Soil Conservation Service. Curve number for the kinematic wave basins were assigned using a procedure similar to that used in the SCS subbasins. For pervious areas, a composite curve number was developed using a weighted average of individual curve numbers for different soil types and, vegetation types and, densities.

The impervious percentage of each subbasin was estimated based on the degree and type of development. For SCS Unit Hydrograph subbasins, the impervious area was used in the development of the composite subbasin curve number. This method was chosen over entering the percent impervious in the model since the SCS Unit Hydrograph methodology assumes impervious areas are directly connected to the outfall and produce instantaneous runoff. In the watershed, the impervious areas are distributed and frequently flow across pervious lands. Modifying the curve number more uniformly distributes the impervious areas over the entire subbasin. For kinematic wave subbasins the actual impervious area percentage is used as an input parameter. An AMC 2 curve number of 98 was used for impervious areas.

Unit Hydrograph Parameters

The SCS Unit Hydrograph runoff option in HEC-1 requires input of the SCS lag, which is equal to the time in hours between the center of mass of rainfall excess and the peak of the unit hydrograph.

The SCS curve number method, as presented in the SCS National Engineering Handbook, Section 4 - Hydrology, was used for calculating lag time. In this method, lag time is a function of the hydraulic length, the slope of the watershed, and the subbasin curve number. The following equation was used to calculate subbasin lag times:

$$L = \frac{l^{0.8}\,(s + 1)^{0.7}}{1900\,Y^{0.5}}$$

Where:
- L = lag in hours
- l = hydraulic length of watershed in feet
- s = $\frac{1000}{CN} - 10$ where CN is the subbasin curve number
- Y = average watershed land slope in percent.

This equation was used to represent basin lag rather than other equations (e.g.. the COE lag equation) because of its application to generally undeveloped subbasins. The COE method, provided comparable lag times in the upper watersheds but resulted in significantly shorter lag times in the flat undeveloped subbasins on the fan. The SCS equation, having been developed for flatter agricultural and range lands, was more representative for use in this study. Developed subbasins for which the SCS equation may not be as applicable are modeled using the kinematic wave overland flow methodology which does not require the input of lag times.

Values for l and Y were determined from USGS 7.5 minute quadrangle maps. Table II-3 presents the calculated lag time.

Kinematic Wave Parameters

For determination of subbasin runoff using the kinematic wave option in HEC-1, information is required about overland flow planes, collector channels and a main channel. Both pervious

and impervious overland flow elements are provided to represent runoff from the subbasin area. Sub-collectors, collectors, and the main channel represent the drainage network in the subbasin. For subbasin runoff generation, basin area, percentage of the area that is impervious, and the length, slope and roughness of pervious and impervious overland flow planes are required input. Percent impervious for each subbasin is presented in Table II-3. Runoff from these flow planes is routed through the drainage network. Parameters used for routing are channel length, slope, roughness, cross-sectional geometry and the contributing area to a typical sub-collector or collector. The kinematic wave parameters were estimated from the USGS 7.5 minute quadrangle maps.

In general, the impervious areas were modeled as having an overland flow length of approximately 50 feet for residential development, to reflect flow length from roof to street flow-line, and 300 feet in commercial and industrial developments, which represents significant parking lot overland flow. A roughness coefficient of 0.1 was used to represent shallow overland flow across impervious areas.

Pervious surface overland flow lengths range between 600 and 800 feet and reflect lawn flow in developed areas or overland flow prior to gully formation in undeveloped areas. A roughness coefficient of 0.2 was used for undeveloped areas and 0.3 for developed lawn areas.

Collector systems in undeveloped areas consisted of small washes. These were modeled in a manner consistent with COE's model using small trapezoidal sections. Developed area collector systems included street sections or improved channels and were modeled to represent actual physical geometry.

FLOOD ROUTING

The kinematic wave flood routing option was used for routing links having well defined, adequate channels. This assumes that there is little floodplain or channel storage and that slopes are steep resulting in the energy grade line slope equalling the ground slope. In areas where this assumption is not appropriate, particularly across the alluvial fan and in developed areas where the drainage system is undersized, the Muskingum storage routing method is used. This method assigns a storage factor to account for the expected attenuation of flows. This study uses the COE values as initial estimates with modification to reflect changes in subbasin delineation and character. Values range from 0.15 for channel reaches across the fan which have some storage in the overbank but few obstructions, to 0.10 for inadequate channels

in developed basins where overbank flows would encounter numerous obstructions and consequently be significantly attenuated.

Kinematic Wave Flood Routing

The kinematic wave approach to channel routing requires the estimation of channel lengths, slopes, average bottom widths, side slopes, and Manning's "n" values. Channel lengths and slopes were estimated from the USGS 7.5 minute quadrangle maps. Average bottom widths, side slopes and "n" values were estimated from mapping, construction drawings, former studies and observations. Length and slope for each routing link, including Muskingum reaches, are presented in Table II-4.

Muskingum Flood Routing

The Muskingum approach to flood routing requires estimation of coefficients that reflect flood wave travel time and channel storage. The "K" factor which approximates flood wave travel time was estimated by the COE in their Feasibility Study. This value is dependent upon length, computational interval and estimated velocity. The "X" values were assigned based on the relative importance of channel storage, with 0.10 for significant storage and 0.15 for lesser degrees of storage. X values for each routing link are presented in Table II-4.

BASIN DEVELOPMENT

General

The hydrologic analysis was performed for both existing basin development and future basin development. Existing conditions reflect present land use and development currently underway. This level of development is generally unchanged from that presented in the Master Plan.

Future conditions refers to the projected extent of development within the Study Area by the year 2055. It represents ultimate development as foreseen today. The boundary of future development was determined using projections from several sources. The boundary used by the COE in their Feasibility Study was adjusted using information from the City of North Las Vegas's Land Use Plan and the Economic Development Department regarding areas of future development in and around the City. COE development limits and those used in this study are shown on Figure II-5. Zoning information from the Clark County Comprehensive Planning Department was used to identify the type and extent of future development.

Future Basin Model

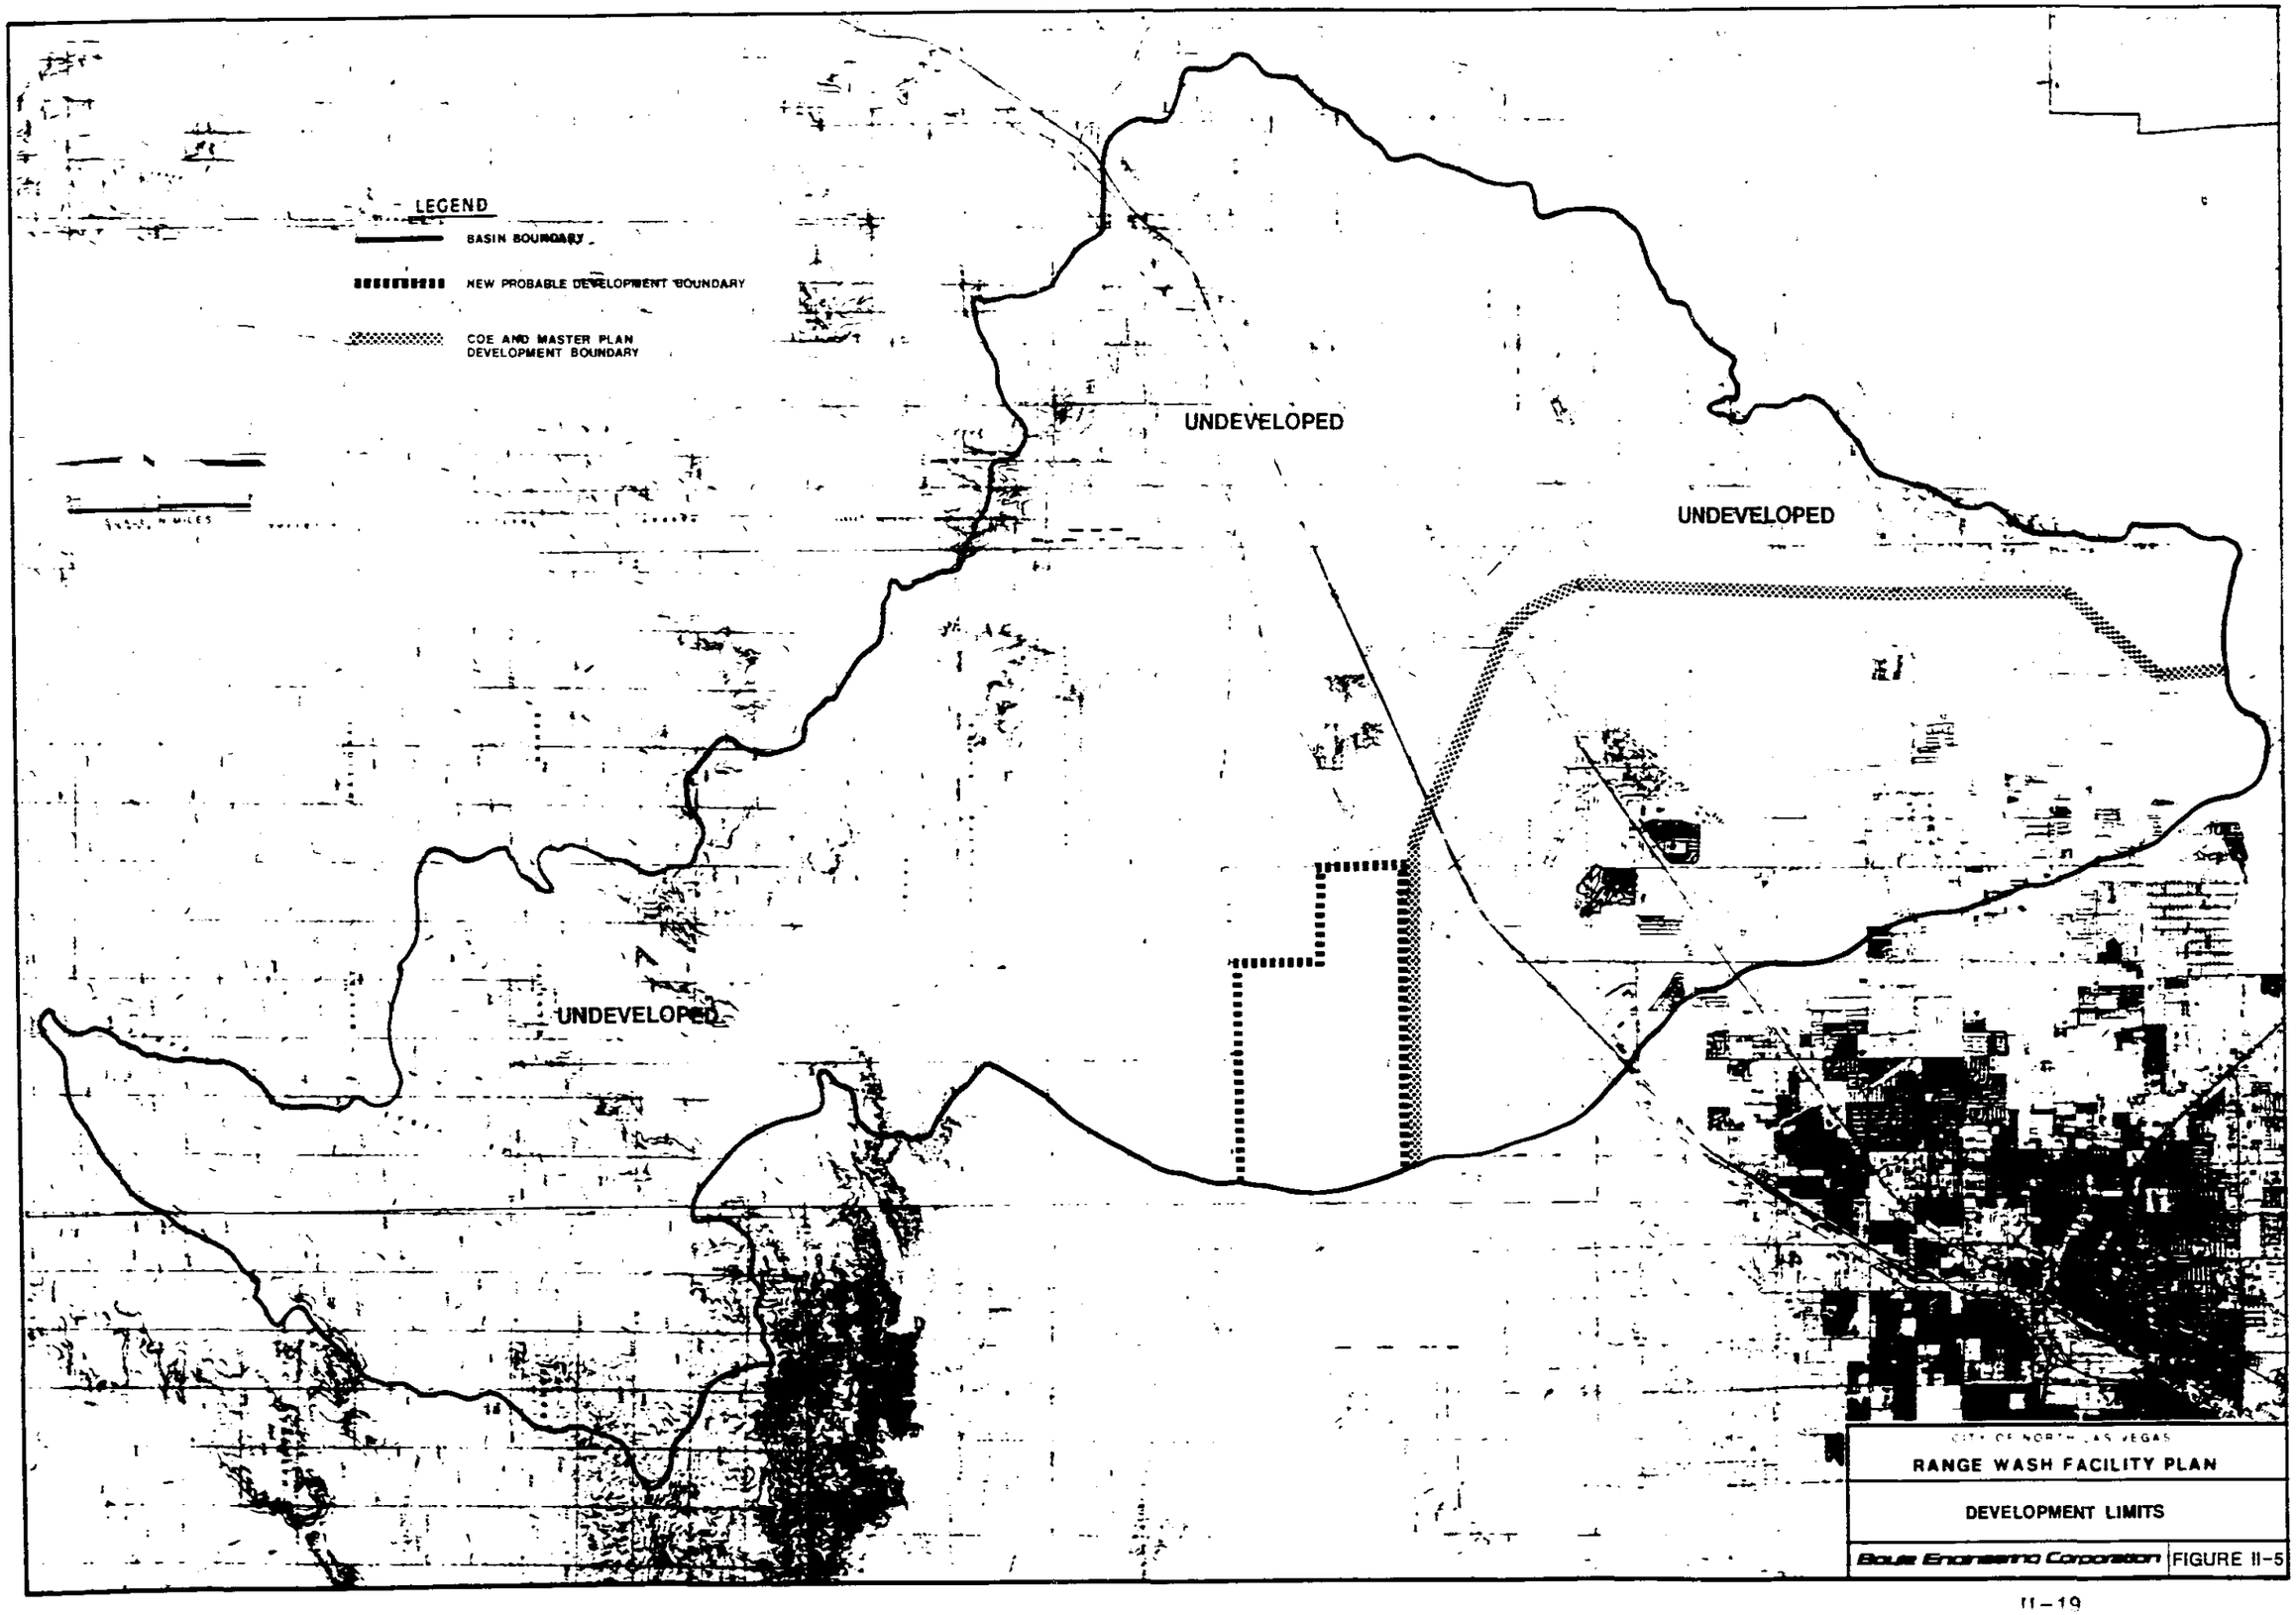
Using the information regarding future land use type and extent, estimates were made of the future amounts of impervious surface, future curve numbers, and changes to the kinematic wave runoff parameters. Future development will increase the amount of impervious surface within a subbasin. The SCS unit hydrograph methodology was selected for basins that would remain generally unchanged after development and therefore model changes were generally nominal and resulted in minor, or no, changes in the curve number. For subbasin 306, the future development scenario calls for virtually full development of a currently undeveloped basin. Runoff characteristics of this basin changed considerably reflecting the significant change between the present and future condition.

In kinematic wave subbasins, increased development resulted in an increase in the percentage of the basin modeled as impervious. In some cases, when the dominant type of development charged, the overland flow characteristics were also changed to reflect altered flow lengths and flow characteristics. Where there was a significant degree of development proposed in a watershed, the pervious area curve number was adjusted downward to reflect a better vegetative cover which would result from improved watering and maintenance. Table II-3 presents the future percent imperviousness and curve numbers.

CALIBRATION

Comparison with Past Studies

Prior to calibration, simulation was performed for the 100-year storm using the parameters as discussed above for the present and future development conditions. The resultant peak flows at the Range Wash Outfall to Las Vegas Wash were 10,880 cfs and 11,380 cfs for the present and future conditions respectively. Table II-5 presents a comparison of Boyle's initial peak



CITY OF NORTH LAS VEGAS
RANGE WASH FACILITY PLAN
DEVELOPMENT LIMITS

COE-C CP1 - present	156.3	8000	51	70
COE-C CP1 - future		8350	53	70
COE-E CP1 - present	156.3	12000	77	70
COE-E CP1 - future		12500	80	70
M.P. RW-326	156.3	16410	105	70

"Initial Boyle" refers to this study before calibration.

"COE-E" refers to Corps of Engineers Feasibility Study, Expected probability flows.

"COE-C" refers to Corps of Engineers, Special Flood Hazard Study, Computed probability flows.

"M.P." refers to CCRFCD Master Plan, Ultimate Development Flows.

The Eastern and Western Tributaries of Range Wash and Range Wash itself are ungaged streams. There is little historical data available for use in calibrating peak flows in a computer model. There are however, several earlier hydrologic studies which attempted to utilize regional calibrated flood events. The most extensive historical and regional analysis was done by the COE as part of their Feasibility Study. The COE conducted an analysis of 36 stations in the California-Nevada desert area with record lengths of greater than 10 years. Using a flood-flow frequency analysis on this data, they developed a regional 100-year peak flow versus drainage area relationship for the Las Vegas Valley. The result of this analysis is a curve which provides a generally accepted range of flow for larger areas. While this curve lumps several hydrologically different watersheds together, the curve does represent an estimate against

which to check the reasonableness of values determined via modeling. Values from this curve are presented in Table II-5 as the Regional Curve Unit Peak Flow.

The COE used the earlier Master Plan model framework as the basis for their computer modeling of the Las Vegas Valley. They developed both Expected and Computed Probability discharge estimates, each based on separate and different statistical assumptions about the data and their reliability. Local governments in the Las Vegas Valley have adopted the Computed Probability estimated flows for regulation purposes within their jurisdictions.

As Table II-5 demonstrates, Boyle's initial peak flow estimates fall between the COE's Expected and Computed Probability estimates and correlate well with the COE regional curves.

In evaluating the differences between the study results presented in Table II-5, several factors appear to be relevant. First, the input parameters for the COE study and Boyle's study are based on many of the same physical assumptions. Routing parameters, subbasins, and routing structure are very similar. The approaches used to model loss rates, however, are different. The COE feasibility study used a constant loss rate whereas Boyle used the SCS curve number method. This has the effect of moderating Boyle's subbasin peak flows since peak losses occur at the time of peak rainfall rather than being constant. Boyle's model also provides a more site specific representation of factors affecting runoff peaks than does the COE model.

Another significant difference in the simulation efforts is the rainfall used in the models. The COE and Boyle used different depth area reduction factors to modify the point precipitation. COE used a DARF developed by their meteorologists which results in a divergence of rainfall amounts for areas over 100 square miles. This DARF curve is inconsistent with the curve presented in HYDRO-40 which is the generally accepted methodology within the Las Vegas Valley. For comparative purposes, Boyle used the COE DARF in the initial model developed for this study and achieved results comparable to the COE computed probability values. As previously identified, the CCRFCD has adopted the COE DARF, however, the final discharges will remain unchanged since the computed probability values are the calibration target.

Calibration Results

The COE calibrated their expected and computed probability model to the peak flow estimates developed from a statistical evaluation of regional gages. This approach forced COE to utilize the same constant loss rate throughout the Valley regardless of soil type or cover.

Calibration of Boyle's model to the COE computed probability peak flows was accomplished in a manner comparable to that used by COE. The Antecedent Moisture Condition (AMC) reflected in the curve numbers was adjusted, thereby effectively changing the losses throughout the watershed. This results in a match of the target computed probability value while maintaining the models ability to reflect varying basin soil and cover characteristics. Curve numbers used in the calibrated present development condition model represent an AMC of 1.8. Calibrated curve numbers are presented in Table II-6. A curve number of 97 was used for impervious areas rather than the 98 used in the initial model.

The projected limits of future development differ between the COE model and Boyle's model. In order to calibrate the Boyle future development model, the future development limit used in the COE model was modeled in Boyle's model. The curve numbers were adjusted by AMC revision until the peak flow at the outfall matched the COE Computed Probability estimate. Calibration of the future condition model resulted in the use of curve numbers representing an AMC of 1.8. The expanded development limits were then introduced into Boyle's model to reflect the information received from the City of North Las Vegas.

SIMULATION RESULTS

Simulations were performed for the 10-, 25-, 50- and 100-year rainfall events for both present and future levels of development. These simulations were run for the temporal and areal rainfall distributions discussed earlier: 1) DARF of 0.62 for the "Total Basin Storm"; 2) DARF of 0.72 for the "Upland Storm" used to model the tributaries to the Master Plan detention ponds; 3) DARF of 0.68 for the "Tributary Basin Storm" above the confluence of the Eastern and Western tributaries; 4) DARF of 0.69 for the "Lower Basin Storm", and; 5) the PMP. Table II-7 presents the resulting peak discharges and volumes for the identified points of interest on East Range Wash, West Range Wash, their confluence and the Range Wash Outfall. The simulated 100-year peak discharges at the Range Wash Outfall for the present and future development conditions, respectively, are 8,040 and 8,870 cfs. Figures II-6 through II-9 present graphical representation of the 100-year present and future development hydrographs.

SEDIMENT YIELD ANALYSIS

Methodology

The sediment yield analysis of the Range Wash Study Area was performed using the Pacific Southwest Interagency (PSIA) methodology. This methodology is intended for broad planning purposes rather than specific project planning. The PSIA methodology considers climate and physical factors of the area, as well as evidence of past erosion, to determine a sediment yield classification for the area in question. The factors consideration: geology, soils, climate, runoff, topography, ground cover, land use, upland erosion, and channel erosion and sediment transport. The factors are each assigned a numeric value based on information obtained from a rating which is used to estimate unit sediment yield.

Basin Discretization

Three watershed subdivisions were selected for analysis using the PSIA methodology: Western Range Wash tributary to the detention facility identified in the master plan (Node F of the Hydrologic analysis); Eastern Range Wash tributary to the detention facility identified in the master plan (Node P1 of the Hydrologic analysis), and; both Washes above their confluence (Node M of the Hydrologic analysis).

Factors Affecting Sediment Yield

The sediment yield analysis factors are summarized below:

Surface Geology: The exposed rock of the study area is predominantly limestone and dolomite, somewhat fractured and weathered. Rock is only exposed in the steep upland areas.

Soils: Soils of the area are generally very gravely with a distinct erosion pavement. Soil material is fine sandy loam with occasional caliche layers and high percentage of rock fragments. A larger extent of caliche was found near the surface in the Eastern Range Wash area than in the western area.

Climate: The Las Vegas Valley has an arid climate with infrequent convective storms and little freeze-thaw occurrence.

Runoff: The Range Wash watersheds produce moderate runoff peak flows and volumes.

Topography: The steep upland slopes have high relief with extensive alluvial fan development at their base. A larger percentage of the western tributary has steep slopes than of the eastern tributary.

Ground Cover: Vegetative ground cover is less than 20 percent. An extensive erosion pavement of rock fragments covers most of the study area.

Land Uses: The majority of the study area is virtually undisturbed except for occasional roads, and mining exploration.

Upland Erosion: The erosion pavement is evidence of upland erosion as are the numerous rills and gullies on the alluvial fans.

Channel Erosion and Sediment Transport: Eroding channel backs are evident where flow is collected either naturally or by man caused means (e.g., roads). Flow is intermittent and of short duration. The eastern tributary is channelized to a slightly higher degree than the western tributary area. The fan above the western ponding area has no well defined channel.

Results

The factors described above were assigned a numeric value representing their relative contribution to the sediment yield of the part of the basin in question. These numeric values were summed and a rating was established. Using curves provided by the PSIA methodology, a unit sediment yield was estimated.

Table II-8 presents a summary of the numeric values assigned to each analysis factor and an estimate of the total average annual sediment production which can be expected at each point of interest.

TABLE II-8

SEDIMENT YIELD ANALYSIS SUMMARY

	Western Tributary	Eastern Tributary	Confluence

Unit Sediment Yield (af/sq mi/yr)	.40	.42	.37
Drainage Area (sq mi)	41	40	133
Sediment Yield			
Estimated Average Annual Sediment Yield (af/yr)	16	17	49

Comparisons with Past Studies

The average annual sediment yield for the three watershed subdivisions is estimated to range from 0.37 af/sq.mi./yr to 0.42 af/sq.mi./yr. The COE feasibility study developed, and presented, a curve of estimated average annual sediment delivery rates to detention basins within the Las Vegas Valley. These curves present sediment delivery per year per square mile versus basin area for areas similar to those found in Range Wash. The COE Feasibility Study estimates were 0.35 af/sq.mi./yr to 0.40 af/sq.mi./yr. This is very close to the values determined in this effort. Differences may be attributed to slightly higher rainfall in the Range Wash watershed than in the Valley as a whole.

Design Storm Sediment Volume

The estimated average annual sediment yield for the Range Wash basin must be converted to a design storm value to be used for channel and other conveyance facility sizing purposes. A review of several studies performed on similar basins in Clark County, Nevada, Mohave County, Arizona and in Southern California indicated that the 100-year sediment volume is generally between four and seven times the average annual volume.

These values were developed primarily using two methods. One method was to develop a Modified Universal Soil loss estimate of sediment delivery for each recurrence interval storm and then integrate over all storm frequencies to establish an average annual sediment delivery volume. The other methodology was to develop an estimate of the sediment yield and sediment transport capacity for each recurrence interval storm and then integrate over all storms to develop an average annual sediment delivery volume.

The ratio of 7 is from a general reference and does not reflect the same level of analysis as the other references. The range of ratios presented in the other reports is between 4 and 5.6 for the 100-year to the average annual. A composite average of 5.26 has been adopted for this study.

Using the adopted 5.26 relationship between the 100-year storm volume and the average annual volume as presented in Table II-8, a 100-year storm sediment volume is computed. Table II-9 presents the estimated 100-year sediment volume.

TABLE II-9

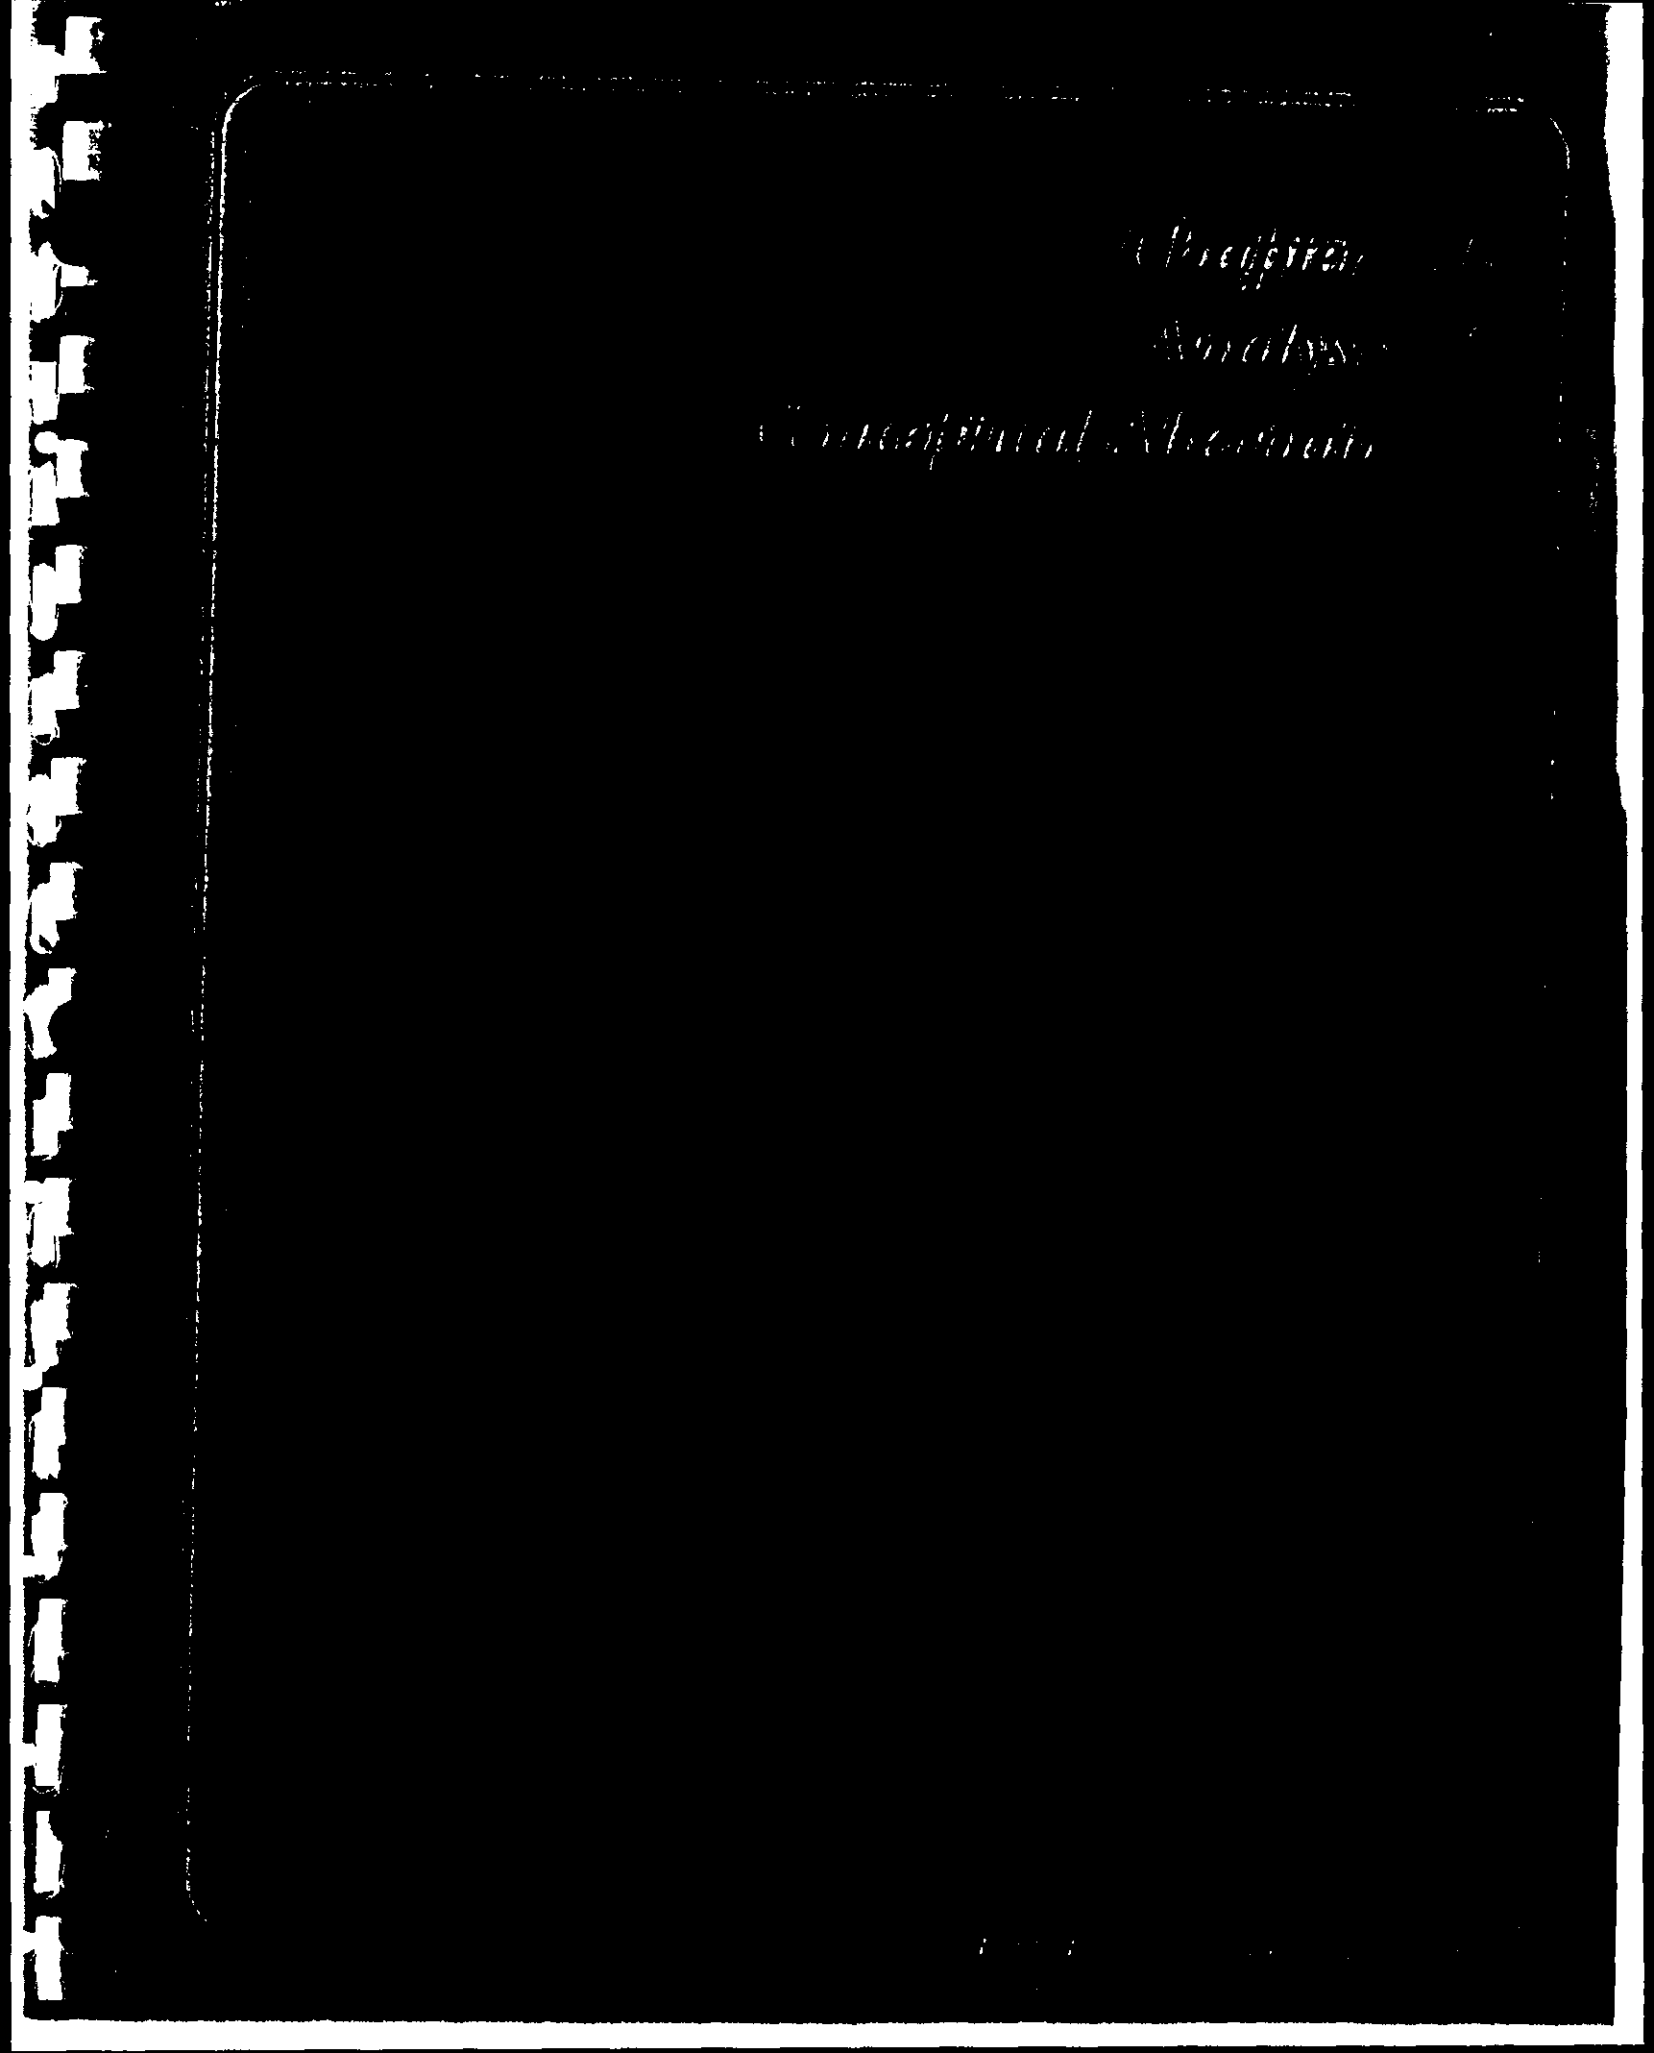
100-YEAR SEDIMENT DELIVERY

	Western Tributary	Eastern Tributary	Confluence
Unit Sediment Yield (AF/MI^2)	2.1	2.2	1.9
100-Year Sediment Yield (AF)	86	88	260

The distribution of this sediment during the hydrograph duration is based on a linear relationship to the discharge rate. Studies have indicated that the relationship of sediment flow to discharge may also follow a power function, however, without calibration, there is no

evidence that a power function provides a better representation and is therefore not used in this study. This distribution can be interpreted as a bulking factor by which clear water discharges can be adjusted to reflect sediment volume.

Using the runoff volumes presented in Table II-7 for the 100-year storm under present basin conditions for each tributary and for the entire basin, the sediment volume constitutes an increase of between 7 and 11%. For this study, a bulking factor of 11% will be utilized for the design of hydraulic facilities subject to sediment laden flows. Facilities below debris basins or other sediment control facilities will use clearwater discharge assumptions.



III - CONCEPTUAL ANALYSIS

INTRODUCTION

The Clark County Regional Flood Control District Master Plan identified a plan for flood control facilities along the Eastern and Western Tributaries of Range Wash. This plan included a series of collector dikes on the alluvial fans of both the Eastern and Western Tributaries of Range Wash. The flow collected along these dikes is conveyed via a stabilized floodway to stormwater detention facilities located on the fan. The stormwater detention basins reduce flows and the subsequent flood hazard downstream. These detention basins are generally located above I-15 and the Union Pacific Railroad tracks, approximately halfway down the alluvial fan. From the outfall of these detention basins, improved channels were proposed. These channels extend to the confluence of the Eastern and Western Tributaries just south of Nellis Air Force Base, and along the existing Sloan Channel alignment to their ultimate outfall in Las Vegas Wash. In addition to the facilities identified along the two major tributaries of Range Wash, smaller debris basins are located on tributaries to the Sloan Channel.

Subsequent to the development and adoption of the Master Plan in 1985, several improvements to the methodologies utilized in the development and evaluation of the plan, and extensive land development within the watershed have made it necessary to update the plan. Utilizing information from subsequent studies, it has been determined that the flow rates presented in the original Master Plan may no longer represent actual flow rates expected during flooding events. The differences in flow rates can be attributed to many factors, including adopted changes in total rainfall depth and areal distribution of rainfall.

The Master Plan, because of its regional scope, used large storms to identify and evaluate regional facilities. Because this study is intended to focus on Range Wash and will ultimately proceed to final design, a more comprehensive evaluation of rainfall and runoff for site specific storm events was required. The resulting revised design discharges at specific locations within the watershed, many of which differ from the Master Plan, are necessary to proceed with final design of proposed facilities. Because the flow rates differ from those in the Master Plan, many of the facility sizes will differ but are necessary accomplish the same flood protection objectives.

Development which has occurred since the adoption of the existing Master Plan has resulted in some of the facilities no longer being feasible in their proposed location or configuration. Many

of the existing improvements constructed along various reaches of Range Wash are not consistent with the intentions of the Master Plan or do not reflect the improved hydrologic techniques. These facilities will be integrated to the extent possible with facilities recommended as part of this basin-wide plan. The limits of ultimate development have also been revised during the intervening years and will have an impact on some of the facilities originally proposed in the Master Plan.

CONCEPTUAL ALTERNATIVE ANALYSIS

Introduction

The development of conceptual alternatives was performed in a manner which utilized, to the extent possible, the information presented in the existing Master Plan. Utilizing this information, plans were developed which satisfied the general objectives of this study. These general objectives are: reduce the flood hazard to existing structures; reduce flood exposure to undeveloped property to allow for greater future development; and, satisfy FEMA requirements for the removal of property from designated floodplains.

Plan Objectives

To reduce flood hazard to existing structures requires that flow be controlled. Controlling flows on the alluvial fan is a difficult task and must be accomplished to direct flows to locations of future downstream facilities. Flood hazard can also be reduced by reducing peak flood discharges. By reducing discharges, residual flood depths and velocities are reduced. The reduction of peak discharges also reduces the size of required downstream facilities necessary to convey the flood flows and minimizes the necessary modifications to existing facilities.

The protection of property designated for future development requires that improvements be made to reduce flood hazard to existing undeveloped properties. This provides greater flexibility for the construction of future developments in areas outside of high flood hazard. These facilities can generally be constructed at relatively low cost because right-of-way, utility and development constraints have not yet been introduced.

To facilitate future development and to reduce the burden of flood insurance premiums on existing properties, the acceptance of any proposed improvements by FEMA is important. FEMA encourages a general fan approach to accomplish this objective. The general fan approach recognizes that there is a statistical likelihood that floods can occur anywhere across

the fan and that protection can most reliably be provided by collecting and controlling flows, and conveying them safely down the fan. FEMA also required that consideration be given to the aggradation and degradation characteristics of the flow and that these considerations be incorporated into the design of facilities.

Alternative Development

Detention is an important element in any plan which addresses the flood hazards on the Range Wash Basin. The Master Plan identifies the benefits of stormwater detention facilities located on the alluvial fan. Detention controls flow by collecting and defining a single point of discharge. In addition, detention reduces the peak flow through storage. This reduces the size of required downstream facilities. An additional benefit to the Range Wash basin is that detention has sediment trapping capabilities. By collecting and detaining floodwaters, water-borne sediments settle out thereby reducing the sediment available for deposition in downstream channel sections.

A review of the results of the hydrologic analysis performed during this study indicates that detention at the confluence of the Western and Eastern Tributaries of Range Wash has a considerable flood reduction benefit. A thunderstorm centered over the lower portion of the basin, below any Master Plan detention basins on the alluvial fan, can result in peak discharges in excess of releases from the detention basins and can exceed the capacity of the Sloan Channel. Detention at the confluence can reduce flows to less than the capacity of the existing Sloan Channel. The detention at the confluence can be constructed before any additional upstream improvements since the confluence is a natural collection point. An immediate benefit will be realized without an extensive upstream collection and conveyance system.

An acceptable level of flow control within the upper reaches of the Range Wash Basin can only be provided through a system of dikes or levees across the alluvial fan. The statistical likelihood of floods on the fan impacting any point is equal, therefore facilities which protect only a portion of the fan provide little protection to areas beyond their physical limits. By constructing dikes, flow can be collected and directed to other facilities for conveyance through the watershed. These dikes can also be constructed in a manner which protects existing developments from flooding. By constructing these facilities immediately upstream of the existing or anticipated future development, that development is protected from fan floods and is only subjected to flooding only from locally-generated runoff. Locally generated flows can be controlled with on-site drainage facilities and will not be addressed in this study.

The construction of improved conveyance systems, either channels, floodways, or pipelines, is another important element in any alternative selected to reduce flooding in the Range Wash Basin. Stabilized conveyance systems can control flows and reduce damage associated with flooding. Existing developed facilities can be protected by confining flows within established rights-of-way. It also enhances future development potential by reducing or eliminating the floodplain associated with natural, uncontrolled flows.

Other Considerations

Several existing flood control facilities exist within the Range Wash Basin which should be integrated into the modified plan. These existing facilities include the Sloan Channel and the Vandenburg Channel. These channels have a capacity less than the 100-year peak discharges. In the case of these and other partially constructed facilities, their alignment is established and therefore limits the potential for changes to channel alignment in their vicinity.

Existing channel crossings also should be incorporated where possible. For example, crossings on the Sloan Channel, at I-15, and at the Union Pacific Railroad all have a fixed capacity and may be inadequate for the conveyance of the existing 100-year peak flows. They also establish horizontal locations and elevations which, if the structures are to be retained, must be incorporated into this plan.

In some cases, existing utilities limit the flexibility of proposed alternatives. Of greatest concern are gravity sanitary sewer lines, which are not easily relocated or adjusted. Other utilities such as water lines, gas lines, and telephone, electric, or TV cables require consideration, but do not present the same constraints as gravity sanitary sewer lines.

Land uses also limit the feasibility of certain alternatives. The proposed Wilderness Study Areas identified on the alluvial fan impose the most restrictions on potential alternatives. The designation may prohibit development or any human impacts in the future. Drainage facilities are inconsistent with Wilderness Study Area designation. Anticipation of future development may also impose similar restrictions on land. The presence of drainage facilities may diminish the flexibility of future development and may offset any potential flood control benefits.

Alternative Description

Based on the foregoing objectives, potential facilities and constraints for alternative plans were identified. The four alternatives are: Master Plan Alternative; Beltway Alignment Alternative;

Master Plan with Confluence Detention Alternative; and Diversion to North Las Vegas Detention Basin Alternative.

Master Plan Alternative

The Master Plan Alternative (Alternative I) represents the alternative proposed in the Clark County Regional Flood Control District Master Plan with minor adjustments to facility location to reflect revised projected development limits. It does not include storm drains and debris basins proposed east of the Sloan Channel. The plan also differs from that presented in the Flood Control District's Master Plan in the sizes of channel and detention facilities. Channels in the current plan are sized to convey local events, therefore the required storage capacity upstream can be reduced to fully utilize the available channel capacity. Revised FEMA requirements for drainage facilities on alluvial fans require more substantial dike structures than those proposed in the current Master Plan. A floodway is also included to convey flows down the Western Tributary alluvial fan to the lower dike location.

The Master Plan Alternative (Figure III-1) includes collection dikes on the Western Tributary alluvial fan with a floodway to convey flows to a detention basin located on the fan, north of the Union Pacific Railroad. A stabilized channel is proposed downstream to the confluence with the Eastern Tributary. A series of diversion dikes is proposed on the Eastern Tributary of Range Wash with a floodway conveying flows to a detention basin located north of I-15. Flows are conveyed in a stabilized channel to the southeast to the confluence with drainage from Area 2 of Nellis Air Force Base. The combined flow is conveyed downstream to the confluence with the Western Tributary after passing through a stormwater detention facility located south and east of Nellis Air Force Base. From the confluence, flows follow the existing Sloan Channel to the ultimate outfall at Las Vegas Wash.

Beltway Alignment Alternative

The Beltway Alignment Alternative (Alternative II shown in Figure III-2) includes a detention facility located on the Western Tributary alluvial fan apex and a diversion dike routing these flows east to a detention facility located on the Eastern Tributary of Range Wash just north of I-15. A stabilized channel extends to the southeast to the confluence with the Nellis Area 2 runoff, and then downstream to the confluence with the Western Tributary of Range Wash. Western Tributary flows are concentrated along the proposed beltway alignment to a detention facility north of I-15 and then in a stabilized channel to the confluence with the Eastern Tributary. A detention basin located at the confluence of the Western and Eastern Tributaries is

included with an outfall to the existing, unimproved Sloan Channel. This alternative minimizes dikes and other alluvial fan facilities which are subject to rigorous scrutiny by FEMA.

Master Plan with Confluence Detention

Alternative III is the Master Plan with Confluence Detention Alternative. This alternative is shown in Figure III-3. This alternative includes the facilities of the Master Plan Alternative (Alternative I) along with detention at the confluence of the Eastern and Western Tributaries to Range Wash. A stormwater detention facility located at this site reduces the required downstream improvements along Sloan Channel.

Diversion to North Las Vegas Wash Detention Basin Alternative

The Diversion to North Las Vegas Wash Detention Basin Alternative (Alternative IV shown in Figure III-4) includes all of the Master Plan with Confluence Detention Alternative facilities along the Eastern Tributary and along the Sloan Channel, however it includes modifications to the Western Tributary facilities. A diversion dike is proposed along the Western Tributary at the approximate location of the Western Tributary Detention Basin proposed in Alternatives I and III. This dike concentrates and conveys alluvial fan flows to the existing North Las Vegas detention basin site. Facilities above the Union Pacific Railroad tracks on the Western Tributary are eliminated. An improved channel is provided from the railroad tracks downstream to the confluence detention facility.

Many of the facilities proposed in these alternatives are common to all the alternatives. To simplify a comparison between the various alternatives, Table III-1, Alternative Facility Matrix has been prepared. This table identifies the various facilities and the alternatives for which these facilities are included.

HYDROLOGIC EVALUATION OF CONCEPTUAL ALTERNATIVES

Introduction

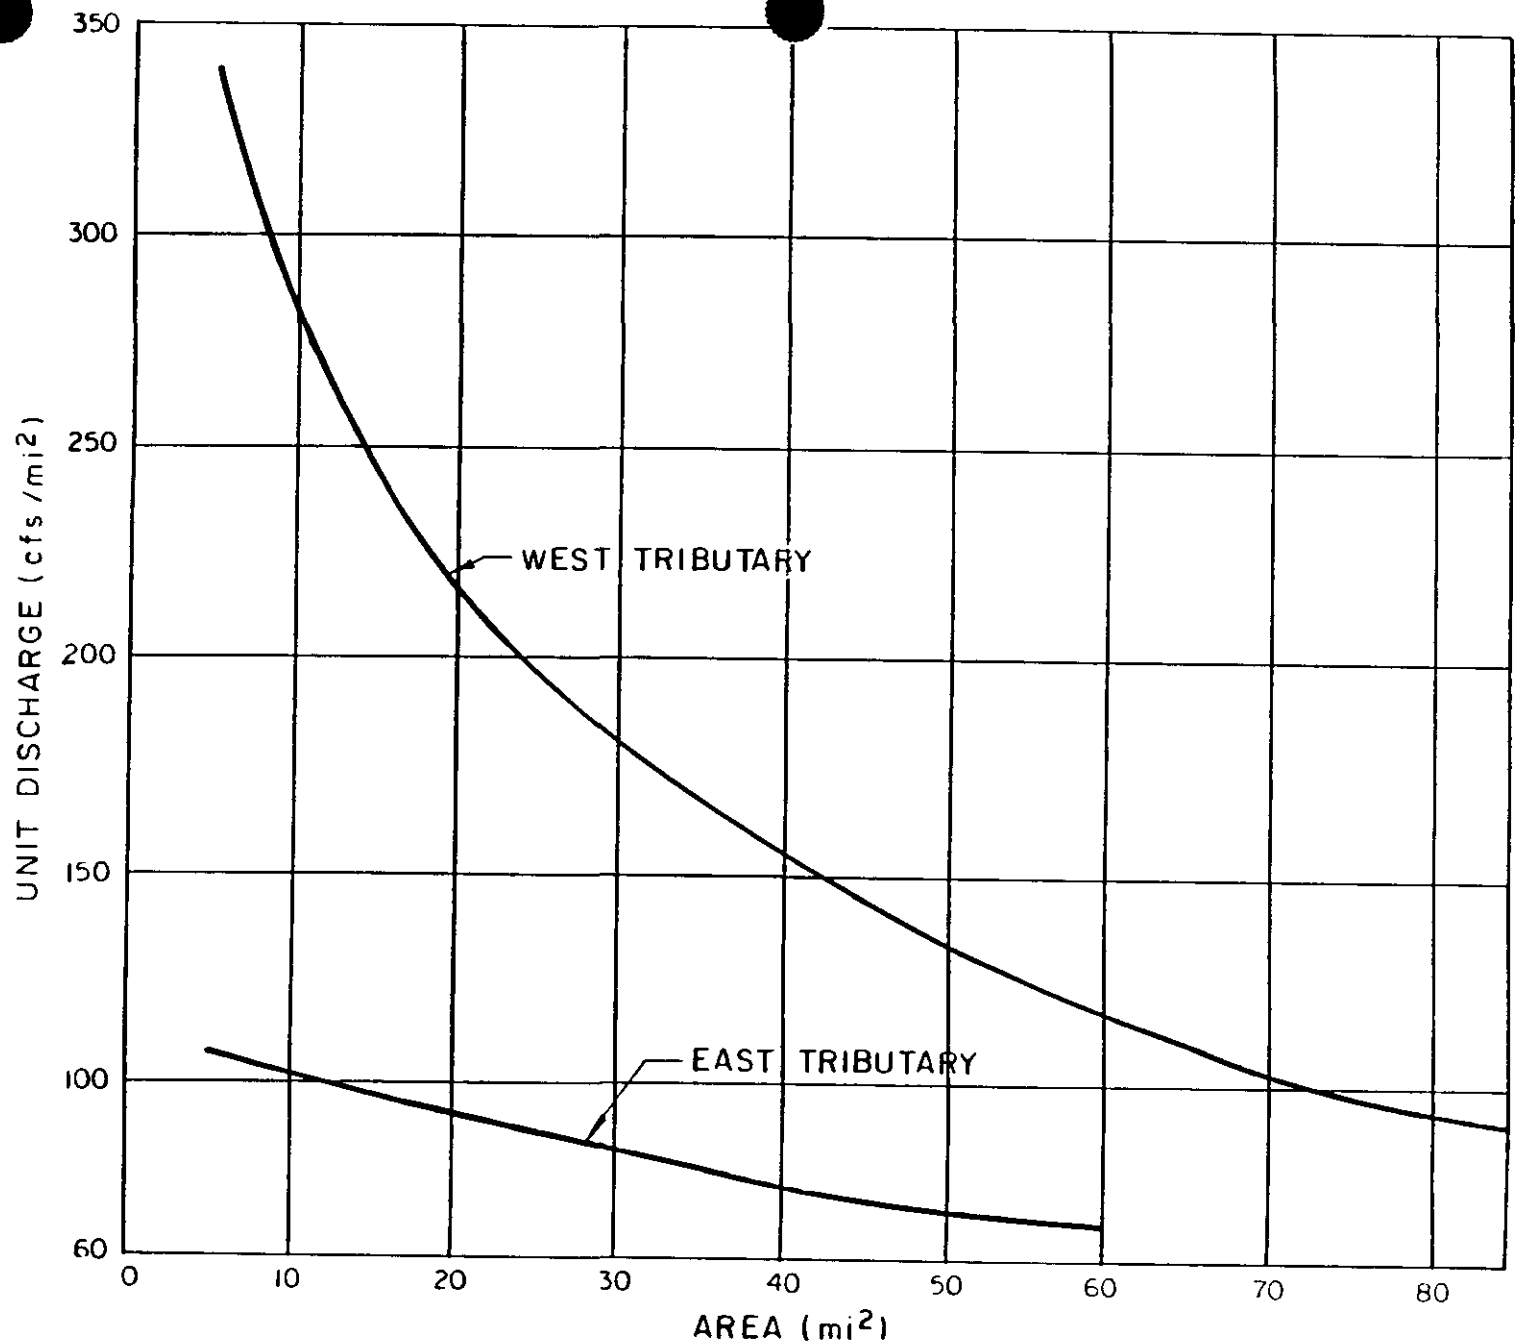
Appropriate methodologies consistent with the purpose and objective of the conceptual analysis were established to perform hydrologic evaluations of the alternatives. Use of these methodologies is predicated on the conceptual nature of the proposed alternatives and a need to evaluate not only basin wide hydrologic events, but to determine spatial distribution of hydrologic events resulting in critical peak discharges and volumes. Methodologies used were: 1) Use of weighted average SCS curve numbers with areally adjusted gross precipitation to estimate inflow volumes to proposed detention basins and 2) Development of unit discharge curves (areal peak discharge versus drainage area) to estimate peak discharges at selected watershed points.

Estimation of Storm Runoff Volumes

Storm runoff volumes were estimated at points of interest within the watershed by determining excess precipitation using the SCS curve number methodology described in Chapter II. Weighted average curve numbers were developed using calibrated curve numbers in Table II-6. Runoff volumes were estimated based on areally adjusted point precipitation values using depth area reduction factors described in Chapter II for the basin area directly tributary to the point of interest.

Unit Discharge Curves

Using the hydrologic model developed in Chapter II for future conditions with existing facilities, unit discharge curves were developed by analyzing storms of different areal extent. For each analysis, precipitation values were adjusted using the appropriate depth area reduction factor for the basin size being analyzed. To account for variation between the hydrologic response of different portions of the watershed, unit discharge curves were developed for both the Western and Eastern Tributaries of Range Wash (Figure III - 5). The unit discharge curves developed illustrate the greater hydrologic response, as measured by peak discharge, of the Western Tributary over that of the Eastern Tributary. This greater response is indicative of differing hydrologic parameters, such as development limits, average land slope and hydrologic soil groups. The Western Tributary has a greater potential for development, a greater average land slope and a greater percentage of soil in SCS hydrologic soil group D. Although use of these unit discharge curves outside the scope of this planning study may be of benefit in estimating



UNIT DISCHARGE CURVES
FIGURE III-5

Boyle Engineering Corporation

order-of-magnitude peak discharges, their use is not considered a substitute for detailed hydrologic investigation and analysis for design of facilities. They are only used for this conceptual analysis and will not be used for preliminary design.

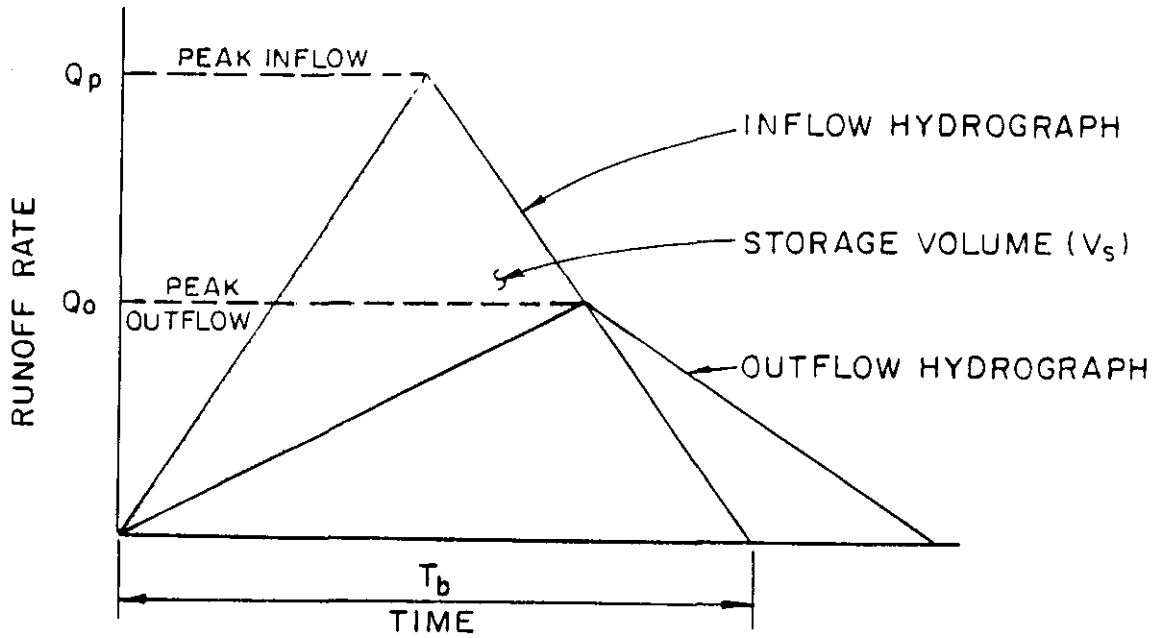
CONCEPTUAL FACILITY SIZING

Approach

The proposed facilities for all alternatives consist of combinations of detention basins, channels and alluvial fan improvements. The approach adopted to size the proposed facilities was to minimize the total cost of all facilities for each alternative. This was accomplished by establishing detention basin volumes by considering the total cost of each detention basin and its associated outlet channel for various detention basin volumes and corresponding outlet channel discharges. Typically an evaluation of this type yields one of three results: 1) Total cost is least with no detention (all conveyance system); 2) Total cost is least with maximum detention (retention system) or; 3) Total cost is least for a detention volume between none and the maximum. This type of analysis is also typically performed for a storm distributed over the area upstream of a proposed detention basin, which ignores the potentially higher unit runoff from a storm distributed over the area downstream of a proposed detention basin. If the results of the analysis indicated maximum detention, then detention basin volumes were reduced such that the peak runoff released to lower outlet channel reaches equalled the flowrate for an intense storm centered downstream of the detention basins. The design peak discharge is the minimum for which the channel can be sized and is independent of basin discharge.

Detention Basins

Detention facility sizing is dependent on runoff volume and its relationship to peak runoff rate, whereas the sizing of the other proposed facilities is predominantly dependent on peak runoff only. Inclusion of upstream detention, which lowers downstream peak runoff rate, generally reduces the size of downstream facilities in a combined system. Methods described in "Urban Stormwater Management," Special Report No. 49, American Public Works Association were used to prepare preliminary storage capacity estimates of proposed detention basins based on estimates of target detention basin outflows. The method uses triangular shapes for both inflow and outflow hydrographs, which provides an expedient means to estimate detention basin volumes for preselected basin outflows. The computational methods are illustrated in Figure III - 6.



$$\text{STORM VOLUME} = V = \frac{T_b Q_p}{2}$$

$$\text{STORAGE VOLUME} = V_s = \frac{T_b}{2}(Q_p - Q_o)$$

$$= V\left(1 - \frac{Q_o}{Q_p}\right)$$

ESTIMATING DETENTION BASIN STORAGE VOLUMES USING TRIANGULAR HYDROGRAPHS

FIGURE III-6

While this method provides reasonable estimates of detention basin storage requirements it does not provide a means of estimating the hydrograph resulting from combining the detention basin outflow hydrograph with downstream inflow hydrographs, unless a relationship regarding the time to peak is known, estimated or assumed. For this analysis it was assumed that 37.5% (3/8) of the runoff volume occurred prior to the peak, which is consistent with the SCS Unit Hydrograph. Therefore, the time to peak of the triangular inflow hydrograph is 37.5% of the hydrograph time base. With the known Q_o the time of the peak outflow can be determined and the shape and time base of the detention basin release hydrograph can be estimated. Combination of runoff hydrographs is important when considering multiple detention basin systems, where design of downstream detention basins is dependent on the ability of upstream detention basins to "delay" the release of storm runoff volume, as well as reduce peak inflow rate.

Channels and Roadway Crossings

Channels were sized based on a height of lining equal to normal depth as given by Manning's equation plus a freeboard allowance of 1.5 feet. Channels downstream of detention basins were assumed to be concrete lined to provide protection from clear water scour. Assumed side slopes for concrete lined channels were 2 horizontal to 1 vertical and bottom widths were based on a channel section producing a maximum flow velocity of 25 feet per second. Where possible, channel velocities were limited to less than 15 feet per second. Manning's n value for concrete lined channels was assumed to be 0.015.

Existing culvert roadway crossings were evaluated on their capability to adequately pass estimated discharge using Bureau of Public Roads "Hydraulic Engineering Circular No. 5" and "Hydraulic Engineering Circular No. 10" based on an allowable headwater one and one-half feet below the roadway overtopping elevation. Record drawings of existing crossings were utilized to obtain geometric data. Existing bridge crossings were evaluated based on open channel hydraulics using the net waterway area and a wetted perimeter which included pier effects. Proposed improvements to roadway crossings without sufficient hydraulic capacity consist of the addition of culvert cells or a replacement structure, depending on the geometry of the crossing. Proposed facilities were sized using the same criteria and methodology used to analyze existing facilities.

Alluvial Fan Improvements

Proposed alluvial fan improvements consist of earthen embankments, which act to concentrate and direct alluvial runoff to selected points; and bank stabilized floodways, which convey runoff to detention basins. Conceptual sizing of these facilities was based on establishing an order-of-magnitude facility size which was consistent with evolving FEMA criteria. New FEMA rule changes have clarified FEMA's position regarding alluvial fan improvements, but do not provide details of acceptable methodologies. In general terms "FEMA will consider for map revision purposes major flood control measures whose design and construction are supported by sound engineering analyses which demonstrate that the measures will effectively eliminate all alluvial fan flood hazard from the area protected by such measures." The engineering analyses referred too must include the following:

1. Quantification of design discharge and volumes of water flow, debris flow and sediment movement associated with the flood that has a one-percent probability of being equaled or exceeded in any year at the apex of the fan under current watershed conditions and under potential adverse conditions (watershed deforestation).

2. Analyses showing that project elements will accommodate the above quantities, and their associated hydrodynamic and hydrostatic forces.

3. Analyses showing design of project elements against erosion and scour.

4. Analyses showing that project elements provide protection from lateral migration and sudden relocation of flows from other parts of the fan.

5. Analysis that assesses method of disposal of concentrated flood water and associated sediment load on adjacent properties.

6. Analysis demonstrating that flooding from local runoff, or sources other than the fan apex, is insignificant, or otherwise has been accommodated.

For this planning study, it is assumed, that the runoff and sediment volume estimates presented in Chapter II meet requirement 1 above. Also, since these runoff estimates include direct rainfall on the fan, below the apex, it is assumed that requirement 6 is met. Requirement 5 is assumed met by discharge of alluvial runoff to detention basins.

Dikes

Element one of the proposed alluvial fan facilities are earthen embankments. To address lateral migration and flow relocation (requirement 4) this study assumed the same design discharge and sediment load at any point along the dike. It was assumed that apex flows reaching the dike would be confined to a single channel with top width equal to that given by Dawdy's equation.

$$T = 9.5Q^{0.4}$$

where

T = Top width of flow (feet)

Q = Discharge (cfs)

This equation also relies on the assumption that the flow forms the channel and the flow regime is critical, i.e. depth of flow is at critical depth. Since the dike is a transverse obstruction to this channel, the hydrodynamic force (requirement 2) of the incoming flow was assumed to be represented by hydrostatic force equal to the depth of flow and velocity head, which conservatively implies that flow is completely stopped before being directed along the toe of the dike. The conveyance area and slope along the dike was determined based on maintaining the flow velocity of the incoming runoff. It was assumed that since the incoming flow represented a state of equilibrium on the fan, then flow along the dike should be similar. It was assumed that a similar velocity distribution would produce a similar state of equilibrium along the dike. To account for sediment deposition (requirement 2) along the dike, especially at the point of impact, a sediment depth was assumed equal to the flow depth along the dike times the percentage of the flow composed of bulked sediment. Prior to performing the sediment yield analysis presented in Chapter II, this percentage was estimated to be 20% based on a 100-year sediment volume equal to ten times the average annual sediment yield. To provide protection against erosion and scour (requirement 3), the upstream dike face was assumed to be soil cemented lined with a lean concrete toe-in equal to the greater of the sediment depth (assumes amount scoured equals potential amount deposited), or a minimum of five feet.

Summarizing, the total design dike height above existing ground elevation is composed of the following four components:

Y_n = normal depth along dike at design discharge, assuming velocity along dike equals fan channel velocity.

Y_v = impact depth, equal to velocity head of fan channel.

Y_s = sediment depth, equal to normal depth times bulking percentage.

Y_f = FEMA minimum freeboard requirement for dikes and levees, equal to three feet.

During the conceptual evaluation it was assumed dikes would be constructed directly on the fan slope using material excavated from floodways, without formation of a channel along the upstream face.

Floodways

Floodways on the fan serve to convey flows concentrated by dikes to existing or proposed alluvial fan detention basins. Conceptual sizing of floodways assumed a top width equal to that given by Dawdy's equation and a total depth equal to critical depth plus three feet of freeboard. Use of Dawdy's regime equation to size floodways is assumed to represent a conservative approach to provide a stable alluvial channel which meets FEMA's requirements 2 and 3. To prevent lateral migration and flow relocation (requirement 4) banks of floodways were assumed to be stabilized by gabions with a toe-in equal to floodway depth. Excavated materials from floodway areas were assumed to be used for dike embankment construction.

CONCEPTUAL FACILITIES

Facilities sized during the conceptual evaluation are presented in tabular form in Appendix B. These tables provide geometric and hydraulic information for each facility of each alternative. Table III-2 compares the peak flow estimated for future development/existing facilities with each alternative at key points within the watershed.

Alternatives I, III and IV have the same percentage peak flow reduction for the Western and Eastern Tributaries at the confluence with Range Wash. However, because Alternatives III and IV include a confluence detention basin, they have a 50 percent greater reduction in peak flow along Range Wash (Sloan Channel), above that for Alternative I. From this comparison, it can

be concluded that inclusion of a confluence detention basin greatly enhances peak flow reduction for Sloan Channel, and diversion of Western Tributary alluvial fan flows has the same effect as a Western Tributary alluvial fan detention basin.

Alternative II provides similar reduction of Sloan Channel peak flows, but further reduces Western Tributary flows at the confluence by a combination of detention and intra-basin diversion to the Eastern Tributary. Whereas Western Tributary peak flows are reduced, no substantial reduction in Eastern Tributary peak flows is obtained.

TABLE III-2

COMPARISON OF 100-YEAR PEAK FLOW (CFS)

Location	Future Development Existing Facilities	Alternative I	II	III	IV
Western Tributary at Confluence	7260	4470	2950	4470	4500
Eastern Tributary at Confluence	3370	860	3100	860	860
Range Wash at Las Vegas Wash	8870	5340	2570	2600	2600

CONCEPTUAL FACILITY COST ESTIMATES

General

Opinions of probable costs for right-of-way and facility construction were prepared for comparing alternatives, and are summarized in Tables III-3, III-4, III-5 and III-6 for alternatives I, II, III and IV, respectively. A contingency of 20 percent of the sum of right-of-way and facility construction cost is included because of the conceptual nature of the facilities. As such, the estimates are opinions of probable cost, subject to changing economic conditions and were developed to allow equal basis comparison of alternatives.

Right-Of-Way Costs

Right-of-way costs are a function of numerous variables, which are not easily defined into monetary values; are best determined on a case-by-case basis with individual property owners;

EASTERN TRIBUTARY	2,200,000	12,000,000	2,800,000	17,000,000
SLOAN CHANNEL	800,000	6,900,000	1,500,000	9,200,000
TOTAL	$ 3,900,000	$36,000,000	$ 7,900,000	$48,000,000

[1] See Figure III-4

and vary both in location and time. The facilities proposed for the various alternatives tend to be located in the following general areas:

1. Historical washes and improved drainage channels with existing right-of-way, such as Sloan Channel, from Las Vegas Boulevard North downstream to Las Vegas Wash and the Vandenberg Channel, from Lone Mountain Road to Craig Road.

2. Various United States public and military reservation lands, such as the proposed alluvial fan improvements and the confluence detention basin.

3. Privately held lands within historical drainage paths located adjacent to military reservations, such as the lower Eastern Tributary Detention Basin and the lower reaches of the Eastern Tributary channel improvements near Nellis Air Force Base.

4. Privately held lands within historical drainage paths and developing urban areas, such as the Western Tributary from Craig Road downstream to Las Vegas Boulevard North.

During the conceptual evaluation, officials at Nellis Air Force Base were contacted regarding recent land acquisitions. The privately held lands being acquired by the Air Force were located within the historical drainage path of the Eastern Tributary of Range Wash. Acquisition costs were between $7,000 and $8,000 per acre. On this basis, $8,000 per acre was assumed appropriate for right-of-way costs for privately held lands. For land within the public domain, or on military reservations, costs were assumed at one-half that for private property, or $4,000 per acre.

Right-of-way widths for lined channels and floodways were calculated as the sum of the channel top width and a minimum allowance of 12 feet for maintenance access, rounded up to the next five feet. Right-of-way areas for detention basins were based on an area necessary to contain the basin with a minimum of 12 feet of access around basin limits.

Facility Construction Costs

General

Opinions of probable construction cost were estimated based on generalized unit costs for the major work quantities which could readily be estimated for the type of facility and its geometry relative to the topographic base mapping used. Identification of all components of work was

not possible, but use of slightly higher unit costs for the major components is considered reasonable to include minor work components.

Detention Basins

Using the detention basin volumes estimated during the conceptual hydrologic evaluation, major cost component quantities, such as excavation and embankment were estimated. Each detention basin site was evaluated and a configuration developed based on balanced earthwork quantities. Detention basins were assumed to consist of an earthen embankment with 3:1 side slopes and a minimum top width of 15 feet. Embankments were assumed to be constructed from materials excavated on-site. No specific embankment or foundation treatments for seepage control were considered because of the relative short duration during which flood waters would be detained. Emergency spillways were assumed to be constructed from built-up soil cement core and were sized for the probable maximum flood (PMF) estimated in Chapter II, with a head not greater than six feet. Because of the steep alluvial fan slopes, "in-ground" detention basins, with excavation volumes exceeding storage volume, were not considered cost-effective. In general, for the configurations and sites evaluated, 25 percent to 40 percent of the storage volume was obtained from required excavations.

Channels and Roadway Crossings

Channels were assumed lined with reinforced concrete 6-inches thick and underlain with an 8-inch granular bedding. Quantities of excavation were estimated assuming excavation of the entire channel section (waterway area, structural section and bedding), except along existing channels, such as Sloan Channel. Roadway culvert crossings and modifications to existing crossings were estimated based qualitative lump sum costs provided from local contractors.

Alluvial Fan Dikes and Floodways

Dikes were assumed to be constructed from material excavated for floodways. Dike side slopes were assumed to be 3 horizontal to 1 vertical with the upstream face lined with an 18-inch thick soil cement blanket placed directly on the slope. A five foot lean concrete cutoff along the upstream toe provides erosion and scour protection. The major work items for floodways consist of bulk excavation and construction of gabions for bank stability. Gabions are constructed with a toe-in equal to floodway depth, based on a three foot gabion basket configuration.

Unit Costs

Table III-7 summarizes the unit costs for major work items used in the development of the conceptual facility cost estimates.

TABLE III-7

UNIT COSTS
MAJOR WORK ITEMS

Description	Unit	Unit Cost
Earthwork	Cubic Yard	$ 3.50
Soil Cement	Cubic Yard	$ 50.00
Gabions	Cubic Yard	$ 100.00
Reinforced Concrete		
Slip-form Channel Lining	Cubic Yard	$ 175.00
Structural Formed	Cubic Yard	$ 400.00
Drain Rock	Ton	$ 14.00

CONCEPTUAL ANALYSIS RESULTS

Introduction

The four conceptual alternatives were analyzed to assess their ability to satisfy identified general objectives and relative construction cost. Results of the qualitative analysis and conceptual cost estimates are used to identify two alternatives which are selected for further consideration.

Qualitative Analysis

As a result of detention and conveyance, all alternatives reduce the hazard of flooding on the Western and Eastern Tributaries and below the confluence. Detention facilities located on the alluvial fan, at the apex of the fan, or above areas of significant development all result in decreased discharges and increased control of flood flows. Dikes also reduce flood hazard by controlling flows.

Alternative I has a lesser degree of flow reduction along the Sloan Channel than the other Alternatives because it does not include the confluence detention basin. The higher residual flows are controlled by proposed improvements to the Sloan Channel and downstream crossings. Alternative II includes an intra-basin diversion of flood waters and relies on

establishment of a Beltway alignment and its relationship to proposed improvements. While the Eastern Tributary facilities are sized to handle flows from the Western Tributary, any intra-basin diversion results in the perception of increased hazard due to the increased frequency of flows reaching that portion of the basin.

Alternative IV also increases the perceived hazard to the adjacent drainage basin. The collection and conveyance of water along the dike from the Western Tributary of Range Wash to the North Las Vegas detention basin, located within the Las Vegas Wash drainage basin, is an inter-basin transfer of water. This transfer increases the frequency and duration of flows in the Las Vegas Wash downstream of the detention basin. The basin is sized to mitigate the flooding impacts downstream, however, the prolonged discharge of water from the detention basin introduces additional problems. Increasing the frequency and duration of flooding in the Las Vegas Wash drainage basin, as a result of flows from the Range Wash basin, is a perceived increase in hazard and may result in increased exposure to liability.

The dikes and channel improvements protect property. The dikes confine and control flows resulting in the downstream area being protected from flood hazard. Channel improvements also control and convey flows thereby protecting adjacent properties from flooding.

The Alternative II beltway diversion provides protection downstream of the proposed beltway. The area upstream of the beltway, below the apex dike and diversion channel, is subject to potential flooding from flows generated on the alluvial fan. The flood peaks are not as high as those flows emanating from the canyon above the apex of the fan, however they are large and generally unconfined, consisting of gully flow, overland flow and flow in small channels. These flows are difficult to control without extensive facilities within a development.

All four alternatives address FEMA requirements as they are currently defined, however FEMA requirements for facilities and improvements on alluvial fans are evolving. The overall fan approach is the standard to which FEMA is measuring alternatives. Because of the evolution of alluvial fan technology, there are no guarantees that this approach will be accepted in the future. Under the current FEMA requirements, facilities which are designed to control alluvial fan flows, which consider sedimentation and the associated aggradation and degradation potential, and those which are appropriately maintained, will be processed and appropriate Letters of Map Revision (LOMR) will be issued. FEMA does reserve the right to change criteria and superimpose revised criteria on existing facilities and existing floodplains. Therefore, while we believe the facilities identified in these alternatives meet the current FEMA criteria, no assurances can be given that a LOMR can be obtained at the time of design or construction.

Cost Comparisons

Costs estimates for the facilities identified in each of the alternatives reflect the conceptual level analysis based on preliminary facility sizes. The cost estimates for each alternative are compared and summarized in Table III-8, Summary of Facility Costs. Estimates include the estimated facility construction cost, the estimated right-of-way cost and the total facility cost, for each alternative.

TABLE III-8

SUMMARY OF FACILITY COSTS
(Millions of Dollars)

Alternative		East Tributary	West Tributary	Sloan Channel	Total
I	Facility	$ 12.0	$ 29.0	$ 9.3	
	Land	2.2	2.3	0.0	
	Contingency	2.8	6.3	1.9	
	Total	$ 17.0	$ 38.0	$ 11.0	$ 66.0
II	Facility	$ 30.0	$ 10.0	$ 6.9	
	Land	1.5	1.1	1.0	
	Contingency	6.3	2.2	1.6	
	Total	$ 38.0	$ 13.0	$ 9.5	$ 61.0
III	Facility	$ 12.0	$ 29.0	$ 6.9	
	Land	2.2	2.3	0.8	
	Contingency	2.8	6.3	1.5	
	Total	$ 17.0	$ 38.0	$ 9.2	$ 64.0
IV	Facility	$ 12.0	$ 17.0	$ 6.9	
	Land	2.2	0.9	0.8	
	Contingency	2.8	3.6	1.5	
	Total	$ 17.0	$ 22.0	$ 9.2	$ 48.0

The estimated conceptual level construction costs for Alternatives I, II and III range from $61 to $66 million. Alternative IV has a substantially lower estimated conceptual level construction cost of $48 million. This reduction in estimated cost stems from the diversion of flows from

Range Wash to the North Las Vegas detention basin. The estimate does not include any modifications to the detention basin nor does it include any channel improvement costs downstream of the basin outlet.

Selected Alternatives

Subsequent to a review of the findings of the conceptual evaluation with the Project Sponsors, Alternatives III and IV were selected for further evaluation and preliminary design. These alternatives feature many common elements including, confluence detention, limited improvements to Sloan Channel, improvements along the Eastern Tributary of Range Wash from the alluvial fan downstream to the confluence, and improvements from the Union Pacific Railroad tracks to the confluence along the Western Tributary. The alternatives differ in their handling of Western Tributary alluvial fan flows. Alternative III provides dikes and a floodway conveying flows to a detention basin located on the alluvial fan and a channelized outflow downstream. Alternative IV consists of the diversion of Western Tributary flows across the alluvial fan to the existing North Las Vegas detention basin.

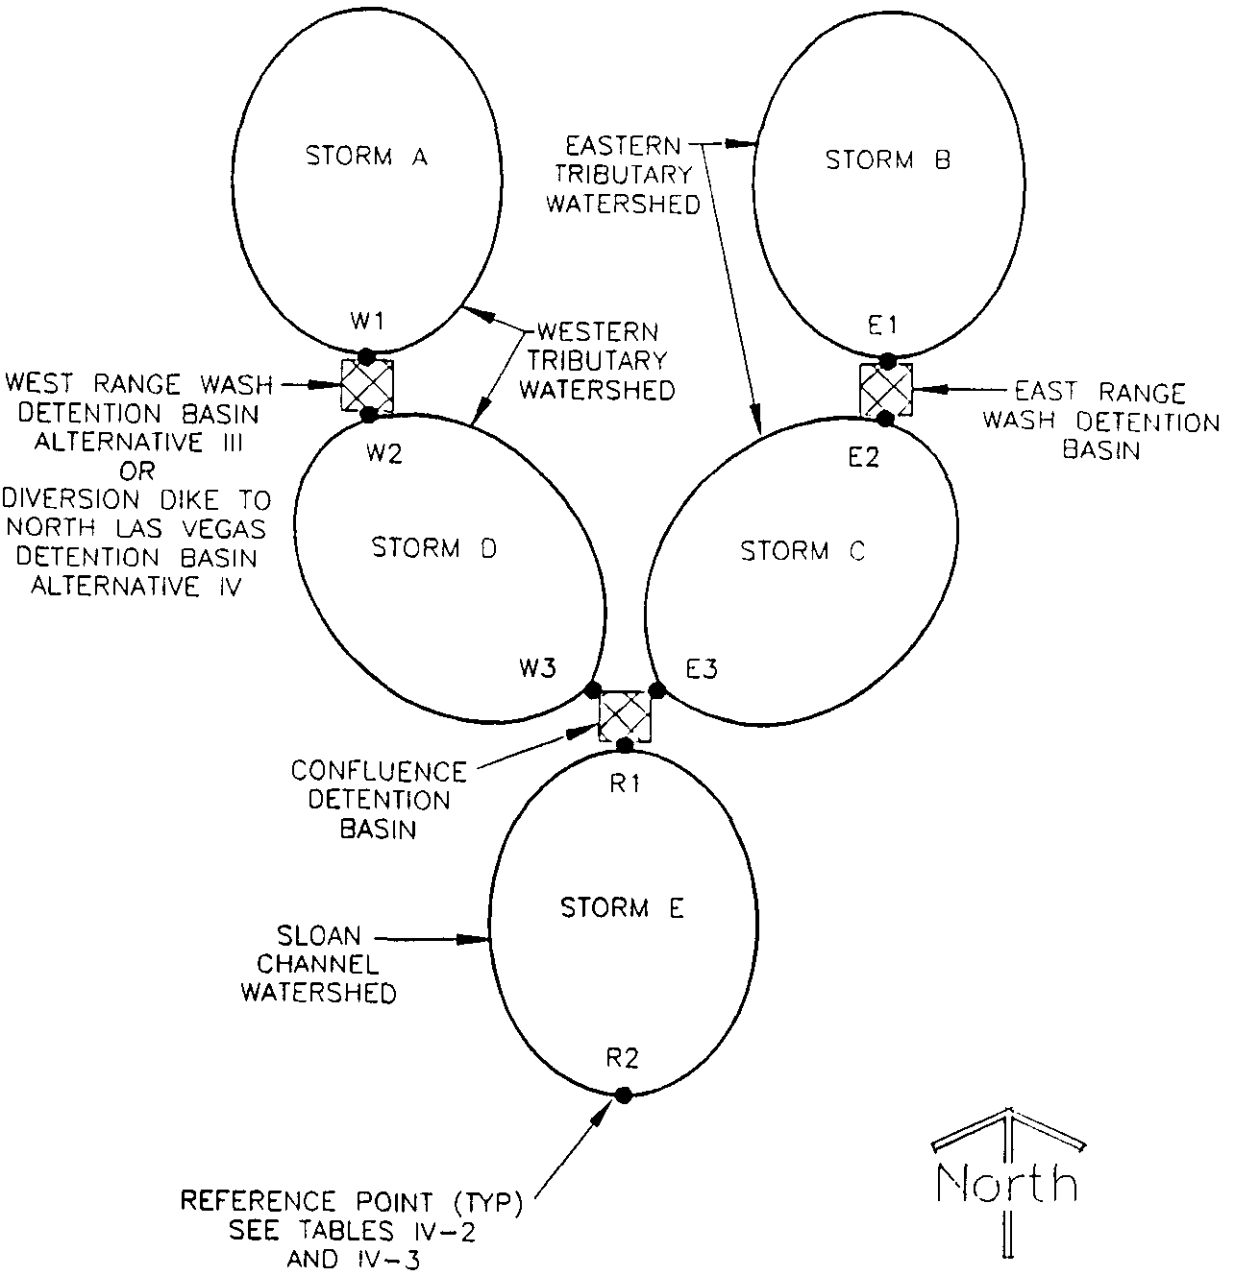
During the review process, the importance of a confluence detention basin to the facility plan became evident. Also, since the lower Eastern Tributary Detention Basin (facility E-P1) is in close proximity to the confluence detention basin and only reduces peak flows for a short reach downstream to the confluence detention basin, project sponsors suggested that only a single confluence detention basin be considered for preliminary design investigations. It was concluded, after further evaluation, that such a plan was feasible and advantageous because of the economics of scale related to cost of a single, large detention basin as opposed to cost of two, moderate sized detention basins.

Subsequent to the identification of these two alternatives, Nellis Air Force Base identified that the confluence detention basin site is an abandoned landfill which may contain hazardous materials. The Air Force is currently evaluating this as a potential Superfund cleanup site. It was determined that an alternative detention basin site would be preferable, if the flood control requirements could be satisfied. After consultation, review and evaluation, an alternative site was identified to the east of Nellis Air Force Base, adjacent to the existing golf course. This site is located on the Eastern Tributary of Range Wash. Moving the detention basin to this location requires a channel across the Nellis Air Force Base golf course to convey Western Tributary flows to the proposed detention basin site. This golf course channel requires integration into the existing golf course and will be earth or grass lined. The alternative detention basin site further justifies the elimination of detention basin E-P1. This is accomplished by enlarging the

size of the previously proposed confluence detention to utilize the additional storage volume available at the newly identified site. This change is include in the evaluation and preliminary design of the two selected alternatives.

The selection of Alternatives III and IV is based largely on the estimated construction cost savings resulting from detention basin construction at the confluence versus the construction of the necessary channel improvements along the Sloan Channel. The difference in cost between these two approaches has been estimated at approximately $2 million. The detention basin also provides an additional benefit in that the construction of the basin along with the golf course channel alone immediate benefits to downstream properties. Because the these facilities are located at the natural low point, extensive upstream facilities are not required to collect the flow and downstream improvements are minimized because of flow reduction.

Alternative II, the Beltway Alignment Alternative, was not selected because of the uncertainty regarding the final beltway alignment and the relationship of the beltway with any proposed drainage improvements. The construction of the beltway diversion dike is a considerable expenditure. The reconstruction of this dike to accommodate an altered beltway alignment would require considerable capital expenditures and was deemed ill-advised at this time.



STORM SCHEMATIC

FIGURE IV-3

Simulation results at key locations within the watershed are summarized in Tables IV - 2 and IV - 3 for Alternative III and Alternative IV, respectively.

Discussion

Comparison of Tables IV-2 and IV-3 indicates that each alternative generally provides the same level of flood control protection. The only significant difference is the Western Tributary below the proposed Western Tributary detention basin for Alternative III. Alternative IV diverts all tributary runoff to the North Las Vegas Detention Basin, thereby reducing the Western Tributary watershed by approximately forty-eight square miles. Therefore, a new watershed beginning point has been established by inclusion of the diversion dike.

Alternative III, with its Western Tributary detention basin, still retains all of the tributary watershed and discharges reduced flows to the lower reaches of the Western Tributary. These clear water outflows are conveyed to the Western Tributary at the Union Pacific Railroad in a stabilized, below grade channel. Critical design discharges (1200 cfs) in the upper reaches of this channel result from a storm centered on the area directly tributary to the detention basin (Western Tributary Upland Storm), whereas the critical design discharge (3400 cfs) for lower reaches results from a storm centered over the upstream and downstream tributary areas (Western Tributary storm).

It is interesting to note that for a storm centered over only the downstream watershed (Western Tributary Lower Basin storm), the estimated peak flow is only 3% less (3300 cfs) than that for the Western Tributary storm (3400 cfs). This is because the Western Tributary alluvial fan detention basin was sized such that lower channel reaches were subject to the same peak flow regardless of whether a storm covered the entire tributary watershed, or the portion downstream of the detention basin. The same observation holds true for the Eastern Tributary detention basin and the confluence detention basin, although to a lesser degree.

FACILITY SIZING

General

Facility sizing criteria used for preliminary design of detention basins, channels and roadway crossings did not differ from that used for the conceptual analysis. This resulted from the lack of site specific mapping of sufficient detail to establish horizontal and vertical alignments beyond a planning level investigation. Where possible, recent drawings of existing channel and

roadway crossing facilities were used to establish channel stationing and grades. Also, where possible, County 1" = 200' topographic mapping was used to obtain more site specific information regarding proposed detention basins, especially the confluence detention basin. Additionally, mapping provided by Nellis Air Force Base was used for the golf course channel.

Alluvial Fan Improvements

Upon completion of the conceptual analysis, the sizing of alluvial fan dikes was revised to include an unlined upstream conveyance section. Previously, no conveyance section was included, and the dike was assumed to be constructed from floodway borrow material. To allow independent construction of floodways and dikes, the conveyance section was added. This revision allows the dike to be constructed from material excavated for the conveyance section and also reduces the total dike height by reducing the depth of flow. All other aspects of dike sizing remain the same.

Subsequent to these changes, representatives from Boyle Engineering Corporation and the City of North Las Vegas met informally with Alan Johnson of FEMA to discuss the proposed approach to handling alluvial fan flows. A brief presentation was made regarding the total fan approach for each alternative and specific mention was made regarding the conceptual facilities, especially proposed dikes. While this was an unofficial meeting, Mr. Johnson appeared receptive to the total fan approach, expressed a desire to work with Project Sponsors regarding the improvements, and seemed to exhibit a positive attitude regarding the proposed facilities. Alluvial fan dikes were discussed and the conceptual dike design approach, including an upstream conveyance section, was positively received. Although this unofficial, informal meeting was positive, Mr. Johnson was not in a position to comment on acceptability until final design and construction of each facility, pursuant to FEMA regulations. However, the positive tone of the meeting indicates the beginning of a cooperative relationship which should be continued during final design.

FACILITY COST ESTIMATES

Opinions of probable cost were estimated for each facility of each alternative and are summarized in Tables IV-4 and IV-5 for Alternatives III and IV, respectively. The same estimating basis was used as that for the conceptual analysis, but reflects a better estimation of quantities obtained from preparation of the drawings presented in Appendix A.

TOTAL	$ 4,300,000	$ 30,830,000	$ 7,030,000	$ 42,160,000

1 See Appendix A Drawings

Table IV-5 summarizes and compares opinions of probable cost for the two alternatives.

TABLE IV - 6

SUMMARY OF PRELIMINARY FACILITY COSTS
(Millions of Dollars)

Alternative		East Tributary	West Tributary	Sloan Channel	Total
III	Facility	$ 11.6	$ 24.8	$ 8.6	
	Land	1.2	3.2	1.9	
	Contingency	2.6	5.6	2.1	
	Total	$ 15.4	$ 33.6	$ 12.6	$ 61.6
IV	Facility	$ 11.6	$ 10.6	$ 8.6	
	Land	1.2	1.2	1.9	
	Contingency	2.6	2.4	2.1	
	Total	$ 15.4	$ 14.2	$ 12.6	$ 42.2

Comparing estimated costs, Alternative IV is the least costly. This results from differing means of handling Western Tributary alluvial fan flows. Alternative IV diverts flows to the existing North Las Vegas Detention Basin, an existing facility, wheras Alternative III requires construction of an alluvial fan detention basin, as well as the collector dikes and floodway required to direct runoff to the basin. However, the estimated cost of Alternative IV does not include costs for modification to the existing detention basin. A concurrent analysis performed by others for the City of North Las Vegas indicates that excess capacity exists within the exiting detention basin, which can be utilized by modification to the exiting outlet works. Costs for this modification are not included in the costs presented in this report.

V - IMPLEMENTATION PLAN

SELECTED ALTERNATIVE

The City of North Las Vegas and the Clark County Regional Flood Control District have selected Alternative IV as their preferred alternative. This alternative features the diversion of Western Tributary flows to the existing North Las Vegas detention basin. It also includes conveyance downstream of Interstate 15 on the Western Tributary and detention and conveyance along the Eastern Tributary from the fan downstream to the confluence with the Western Tributary. Detention is proposed at the confluence and limited channel improvements are required downstream before discharging into the Las Vegas Wash.

This plan utilizes existing facilities to the greatest extent practicable by limiting flow rates to existing capacities or adding limited facilities to inadequate existing structures. New facilities are proposed where no existing facilities are in place or where existing facilities are not compatible with proposed ones. By adopting this approach, the desired flood protection is provided at lower cost.

COORDINATION WITH MASTER PLAN UPDATE

Subsequent to the initiation of this study, the Clark County Regional Flood Control District authorized a project to update the existing Clark County Master Plan. Boyle worked closely with the District's consultant, James M. Montgomery, to incorporate the findings of the facility planning study into the Master Plan Update.

The Master Plan Update hydrology is based on the hydrologic model developed by Boyle. Some modifications were made to incorporate recently adopted hydrologic criteria. The discharges developed during the Master Plan Update are consistent with those of this study and therefore do not require any modification of the recommended plan. For regulatory purposes, the Master Plan Update has adopted the discharges which reflect the diversion dike (Facility W-1) superimposed on the existing watershed. This reflects the assumption that the construction of this facility will occur in the near future.

The facilities recommended in this Facility Plan have been incorporated into the Master Plan Update with nominal modification. Some additional facilities are proposed between the

diversion dike (W-1) and Interstate 15 to collect and convey flows expected during future development. These facilities were not included in this study because it was believed that needlessly encumbered development of this area and would be more appropriately planned, designed and constructed by the developer at the time of development. The master plan update also includes runoff control of the east side drainages which are directly tributary to Sloan Channel. These facilities were included at the request of Clark County in response to historic debris and sedimentation problems experienced along the roadways. They were not included in the facility plan because they did not affect the sizing of facilities along Sloan Channel and because any flood flows would flow down existing streets or drainages and ultimately reach Sloan Channel regardless of the extent of improvements.

The Master Plan Update summarizes and incorporates the findings of this study. While only a Facility Plan, this study contains a more detailed presentation of the Alternative plan than does the Master Plan Update. Plan and Profile drawings with preliminary alignments and grades are provided as part of this study. This Facility Plan is intended to provide the foundation for final design by identifying significant constraints and identifying a geometry and alignment which best reconciles the identified constraints. At the time of final design, more detailed mapping will be required to provide enough information to confirm the preliminary alignment and geometry and allow reconciliation of remaining problem areas.

IMPLEMENTATION PLAN

Because sufficient funds are not available to construct all the facilities identified in this plan, an implementation plan has been formulated. The plan weighs the need for the improvements along with the cost and relative benefit to develop a priority list. Using the criteria, two facilities are of highest priority; the Western Tributary diversion dike and the confluence detention basin.

The importance of the Western Tributary dike and the resulting flow reduction has long been recognized. The existing Master Plan identifies a detention basin which achieves the same objective as does dike construction. This facility was funded in the District's 10-year program. Since the dike serves the same function, at lower cost, its priority is clear. The timeliness of this is even more evident given the ongoing development pressures which exist on this portion of the fan.

Past flooding, and the highest degree of residential development, have occurred along the Sloan Channel. To most cost effectively reduce the flooding and subsequent damage, the confluence detention basin should be constructed. To collect western tributary flows, the golf

course channel must be constructed concurrently. The existing master plan did not include the facility, therefore, it is not included in any identified funding program. It has been included in the Master Plan Update and will be eligible for future inclusion.

The remaining facilities are all important parts of this plan and are vital to provide the required level of flood protection. The following table presents a recommended priority listing of the facilities identified in this plan.

TABLE V - 1

IMPLEMENTATION PRIORITY

Priority	Facility Description	Facility Designation
1A	Western Tributary Diversion Dike	Dike W-1
1B	Confluence Detention Basin and Golf Course Channel	Basin R-M and Channel W-9D
2	Property Acquisition for East Tributary Detention Basin	Basin E-J1 land
3	Sloan Channel Improvements	Channels R-1 to R-7
4	West Tributary Channel from from UPRR to Golf Course Channel	Channels W-6 to W-9
5	East Tributary Detention Basin and Channel to Forrestal	Basin E-J1 and Channels E-4 and E-5
6	East Tributary Floodway and dikes upstream of Detention Basin	Dike E-1A and Floodway E-2A
7	East Tributary Channel Forrestal to Confluence Detention Basin	Channels E-6 and E-7

These priorities represent conditions which exist within the basin at the present time. It is advisable to review these priorities periodically and reassess their applicability to current needs.

If opportunities for the construction of lower rated improvements become available, they should be encouraged, particularly if private funds are suggested for the construction.

HYDROLOGIC EVALUATION OF CONCEPTUAL ALTERNATIVES

Introduction

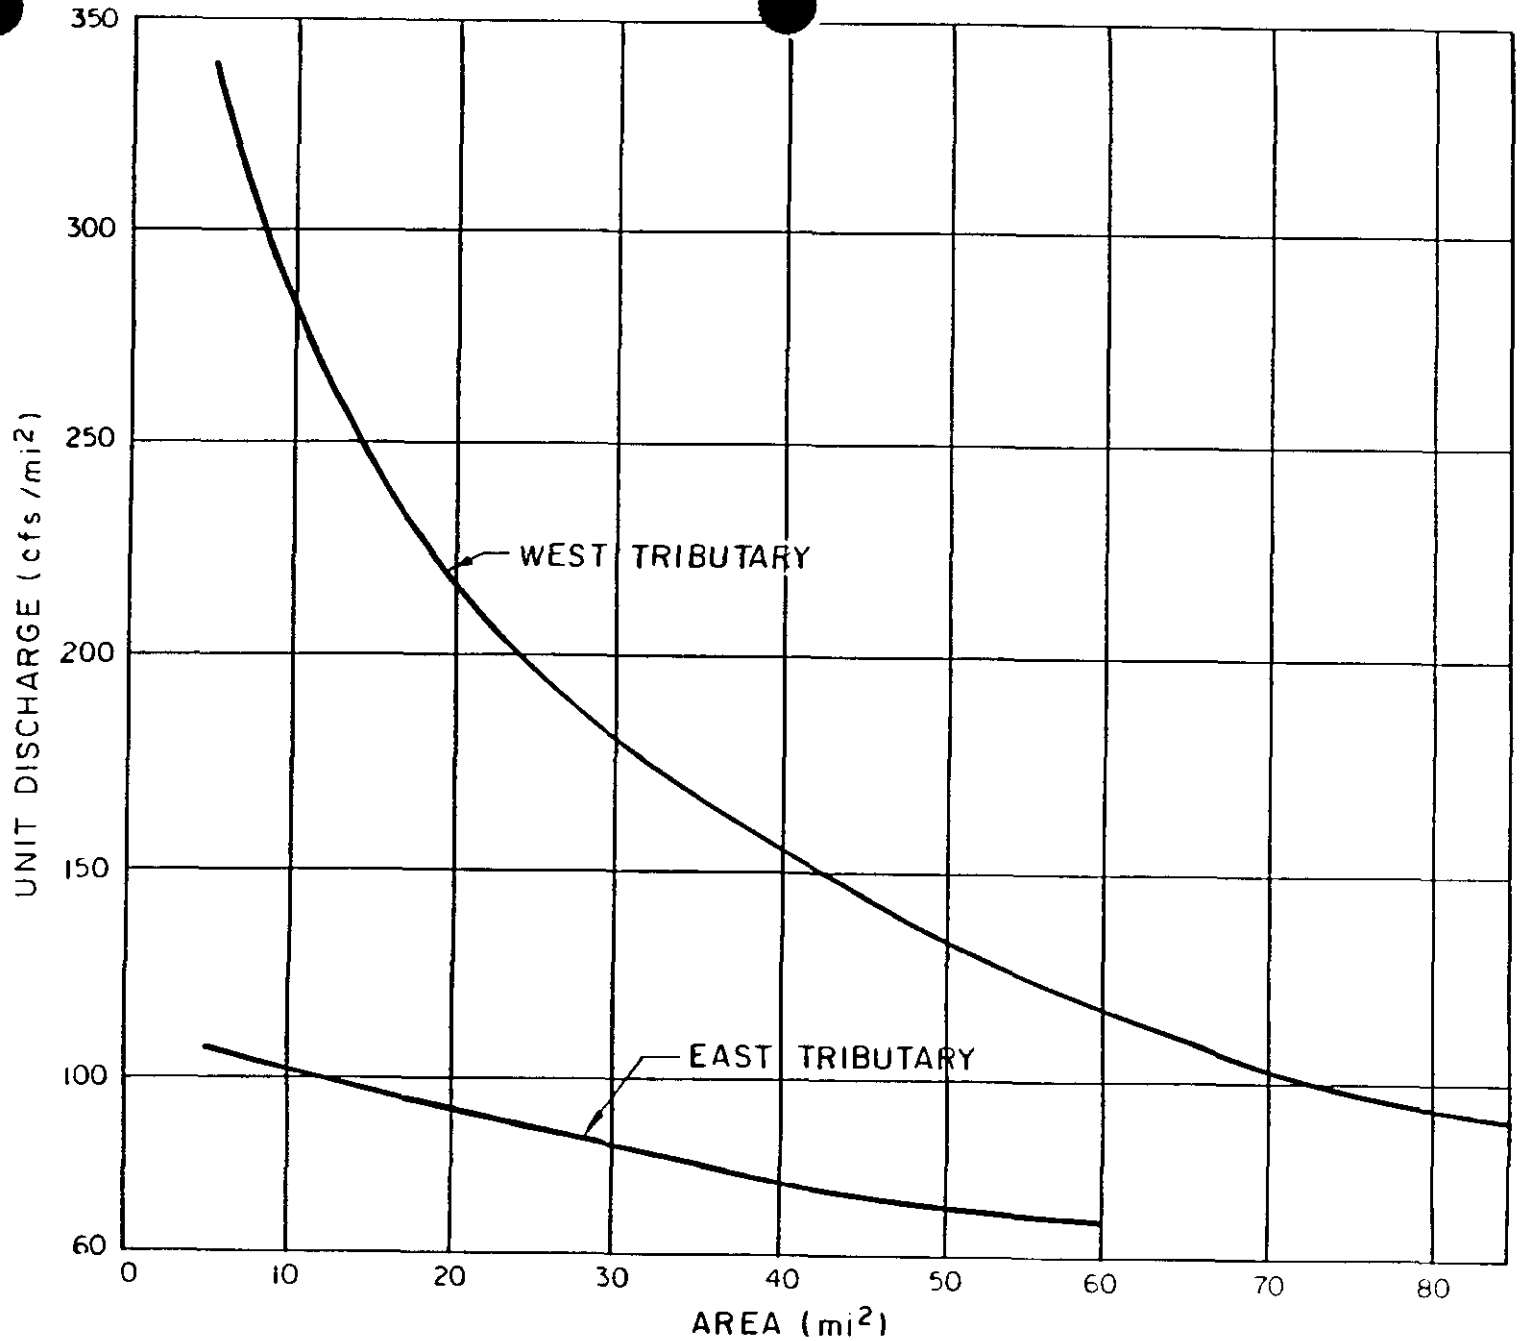
Appropriate methodologies consistent with the purpose and objective of the conceptual analysis were established to perform hydrologic evaluations of the alternatives. Use of these methodologies is predicated on the conceptual nature of the proposed alternatives and a need to evaluate not only basin wide hydrologic events, but to determine spatial distribution of hydrologic events resulting in critical peak discharges and volumes. Methodologies used were: 1) Use of weighted average SCS curve numbers with areally adjusted gross precipitation to estimate inflow volumes to proposed detention basins and 2) Development of unit discharge curves (areal peak discharge versus drainage area) to estimate peak discharges at selected watershed points.

Estimation of Storm Runoff Volumes

Storm runoff volumes were estimated at points of interest within the watershed by determining excess precipitation using the SCS curve number methodology described in Chapter II. Weighted average curve numbers were developed using calibrated curve numbers in Table II-6. Runoff volumes were estimated based on areally adjusted point precipitation values using depth area reduction factors described in Chapter II for the basin area directly tributary to the point of interest.

Unit Discharge Curves

Using the hydrologic model developed in Chapter II for future conditions with existing facilities, unit discharge curves were developed by analyzing storms of different areal extent. For each analysis, precipitation values were adjusted using the appropriate depth area reduction factor for the basin size being analyzed. To account for variation between the hydrologic response of different portions of the watershed, unit discharge curves were developed for both the Western and Eastern Tributaries of Range Wash (Figure III - 5). The unit discharge curves developed illustrate the greater hydrologic response, as measured by peak discharge, of the Western Tributary over that of the Eastern Tributary. This greater response is indicative of differing hydrologic parameters, such as development limits, average land slope and hydrologic soil groups. The Western Tributary has a greater potential for development, a greater average land slope and a greater percentage of soil in SCS hydrologic soil group D. Although use of these unit discharge curves outside the scope of this planning study may be of benefit in estimating



UNIT DISCHARGE CURVES
FIGURE III-5

Boyle Engineering Corporation

order-of-magnitude peak discharges, their use is not considered a substitute for detailed hydrologic investigation and analysis for design of facilities. They are only used for this conceptual analysis and will not be used for preliminary design.

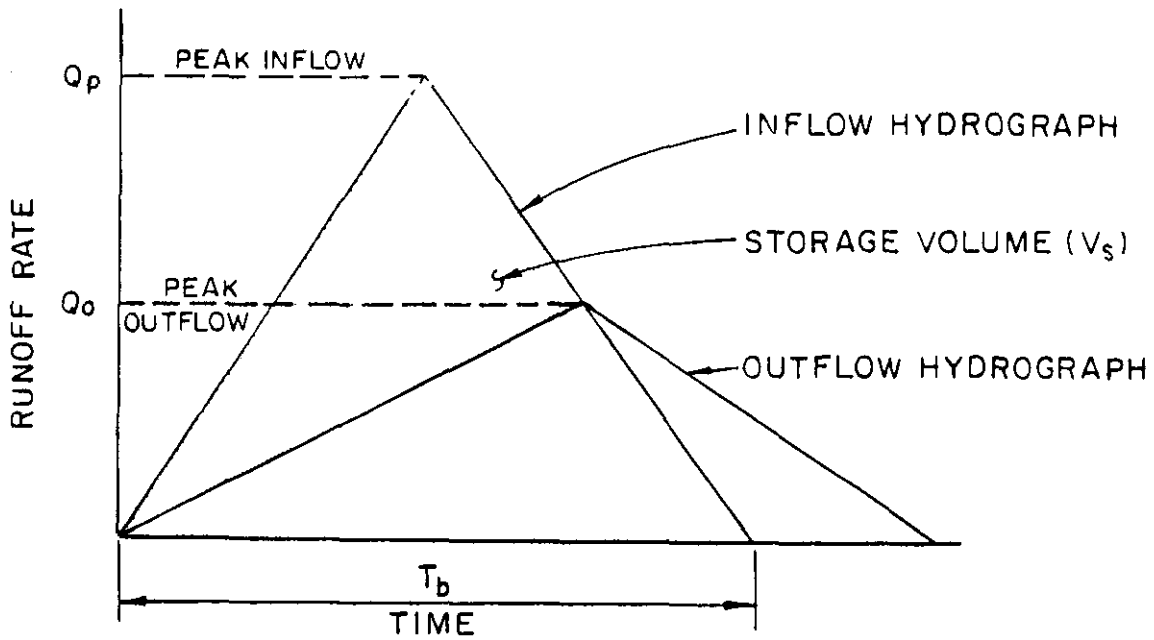
CONCEPTUAL FACILITY SIZING

Approach

The proposed facilities for all alternatives consist of combinations of detention basins, channels and alluvial fan improvements. The approach adopted to size the proposed facilities was to minimize the total cost of all facilities for each alternative. This was accomplished by establishing detention basin volumes by considering the total cost of each detention basin and its associated outlet channel for various detention basin volumes and corresponding outlet channel discharges. Typically an evaluation of this type yields one of three results: 1) Total cost is least with no detention (all conveyance system); 2) Total cost is least with maximum detention (retention system) or; 3) Total cost is least for a detention volume between none and the maximum. This type of analysis is also typically performed for a storm distributed over the area upstream of a proposed detention basin, which ignores the potentially higher unit runoff from a storm distributed over the area downstream of a proposed detention basin. If the results of the analysis indicated maximum detention, then detention basin volumes were reduced such that the peak runoff released to lower outlet channel reaches equalled the flowrate for an intense storm centered downstream of the detention basins. The design peak discharge is the minimum for which the channel can be sized and is independent of basin discharge.

Detention Basins

Detention facility sizing is dependent on runoff volume and its relationship to peak runoff rate, whereas the sizing of the other proposed facilities is predominantly dependent on peak runoff only. Inclusion of upstream detention, which lowers downstream peak runoff rate, generally reduces the size of downstream facilities in a combined system. Methods described in "Urban Stormwater Management," Special Report No. 49, American Public Works Association were used to prepare preliminary storage capacity estimates of proposed detention basins based on estimates of target detention basin outflows. The method uses triangular shapes for both inflow and outflow hydrographs, which provides an expedient means to estimate detention basin volumes for preselected basin outflows. The computational methods are illustrated in Figure III - 6.



$$\text{STORM VOLUME} = V = \frac{T_b Q_p}{2}$$

$$\text{STORAGE VOLUME} = V_s = \frac{T_b}{2}(Q_p - Q_o)$$

$$= V\left(1 - \frac{Q_o}{Q_p}\right)$$

ESTIMATING DETENTION BASIN STORAGE VOLUMES USING TRIANGULAR HYDROGRAPHS

FIGURE III-6

While this method provides reasonable estimates of detention basin storage requirements it does not provide a means of estimating the hydrograph resulting from combining the detention basin outflow hydrograph with downstream inflow hydrographs, unless a relationship regarding the time to peak is known, estimated or assumed. For this analysis it was assumed that 37.5% (3/8) of the runoff volume occurred prior to the peak, which is consistent with the SCS Unit Hydrograph. Therefore, the time to peak of the triangular inflow hydrograph is 37.5% of the hydrograph time base. With the known Q_o the time of the peak outflow can be determined and the shape and time base of the detention basin release hydrograph can be estimated. Combination of runoff hydrographs is important when considering multiple detention basin systems, where design of downstream detention basins is dependent on the ability of upstream detention basins to "delay" the release of storm runoff volume, as well as reduce peak inflow rate.

Channels and Roadway Crossings

Channels were sized based on a height of lining equal to normal depth as given by Manning's equation plus a freeboard allowance of 1.5 feet. Channels downstream of detention basins were assumed to be concrete lined to provide protection from clear water scour. Assumed side slopes for concrete lined channels were 2 horizontal to 1 vertical and bottom widths were based on a channel section producing a maximum flow velocity of 25 feet per second. Where possible, channel velocities were limited to less than 15 feet per second. Manning's n value for concrete lined channels was assumed to be 0.015.

Existing culvert roadway crossings were evaluated on their capability to adequately pass estimated discharge using Bureau of Public Roads "Hydraulic Engineering Circular No. 5" and "Hydraulic Engineering Circular No. 10" based on an allowable headwater one and one-half feet below the roadway overtopping elevation. Record drawings of existing crossings were utilized to obtain geometric data. Existing bridge crossings were evaluated based on open channel hydraulics using the net waterway area and a wetted perimeter which included pier effects. Proposed improvements to roadway crossings without sufficient hydraulic capacity consist of the addition of culvert cells or a replacement structure, depending on the geometry of the crossing. Proposed facilities were sized using the same criteria and methodology used to analyze existing facilities.

Alluvial Fan Improvements

Proposed alluvial fan improvements consist of earthen embankments, which act to concentrate and direct alluvial runoff to selected points; and bank stabilized floodways, which convey runoff to detention basins. Conceptual sizing of these facilities was based on establishing an order-of-magnitude facility size which was consistent with evolving FEMA criteria. New FEMA rule changes have clarified FEMA's position regarding alluvial fan improvements, but do not provide details of acceptable methodologies. In general terms "FEMA will consider for map revision purposes major flood control measures whose design and construction are supported by sound engineering analyses which demonstrate that the measures will effectively eliminate all alluvial fan flood hazard from the area protected by such measures." The engineering analyses referred too must include the following:

1. Quantification of design discharge and volumes of water flow, debris flow and sediment movement associated with the flood that has a one-percent probability of being equaled or exceeded in any year at the apex of the fan under current watershed conditions and under potential adverse conditions (watershed deforestation).

2. Analyses showing that project elements will accommodate the above quantities, and their associated hydrodynamic and hydrostatic forces.

3. Analyses showing design of project elements against erosion and scour.

4. Analyses showing that project elements provide protection from lateral migration and sudden relocation of flows from other parts of the fan.

5. Analysis that assesses method of disposal of concentrated flood water and associated sediment load on adjacent properties.

6. Analysis demonstrating that flooding from local runoff, or sources other than the fan apex, is insignificant, or otherwise has been accommodated.

For this planning study, it is assumed, that the runoff and sediment volume estimates presented in Chapter II meet requirement 1 above. Also, since these runoff estimates include direct rainfall on the fan, below the apex, it is assumed that requirement 6 is met. Requirement 5 is assumed met by discharge of alluvial runoff to detention basins.

Dikes

Element one of the proposed alluvial fan facilities are earthen embankments. To address lateral migration and flow relocation (requirement 4) this study assumed the same design discharge and sediment load at any point along the dike. It was assumed that apex flows reaching the dike would be confined to a single channel with top width equal to that given by Dawdy's equation.

$$T = 9.5Q^{0.4}$$

where

T = Top width of flow (feet)

Q = Discharge (cfs)

This equation also relies on the assumption that the flow forms the channel and the flow regime is critical, i.e. depth of flow is at critical depth. Since the dike is a transverse obstruction to this channel, the hydrodynamic force (requirement 2) of the incoming flow was assumed to be represented by hydrostatic force equal to the depth of flow and velocity head, which conservatively implies that flow is completely stopped before being directed along the toe of the dike. The conveyance area and slope along the dike was determined based on maintaining the flow velocity of the incoming runoff. It was assumed that since the incoming flow represented a state of equilibrium on the fan, then flow along the dike should be similar. It was assumed that a similar velocity distribution would produce a similar state of equilibrium along the dike. To account for sediment deposition (requirement 2) along the dike, especially at the point of impact, a sediment depth was assumed equal to the flow depth along the dike times the percentage of the flow composed of bulked sediment. Prior to performing the sediment yield analysis presented in Chapter II, this percentage was estimated to be 20% based on a 100-year sediment volume equal to ten times the average annual sediment yield. To provide protection against erosion and scour (requirement 3), the upstream dike face was assumed to be soil cemented lined with a lean concrete toe-in equal to the greater of the sediment depth (assumes amount scoured equals potential amount deposited), or a minimum of five feet.

Summarizing, the total design dike height above existing ground elevation is composed of the following four components:

Y_n = normal depth along dike at design discharge, assuming velocity along dike equals fan channel velocity.

Y_v = impact depth, equal to velocity head of fan channel.

Y_s = sediment depth, equal to normal depth times bulking percentage.

Y_f = FEMA minimum freeboard requirement for dikes and levees, equal to three feet.

During the conceptual evaluation it was assumed dikes would be constructed directly on the fan slope using material excavated from floodways, without formation of a channel along the upstream face.

Floodways

Floodways on the fan serve to convey flows concentrated by dikes to existing or proposed alluvial fan detention basins. Conceptual sizing of floodways assumed a top width equal to that given by Dawdy's equation and a total depth equal to critical depth plus three feet of freeboard. Use of Dawdy's regime equation to size floodways is assumed to represent a conservative approach to provide a stable alluvial channel which meets FEMA's requirements 2 and 3. To prevent lateral migration and flow relocation (requirement 4) banks of floodways were assumed to be stabilized by gabions with a toe-in equal to floodway depth. Excavated materials from floodway areas were assumed to be used for dike embankment construction.

CONCEPTUAL FACILITIES

Facilities sized during the conceptual evaluation are presented in tabular form in Appendix B. These tables provide geometric and hydraulic information for each facility of each alternative. Table III-2 compares the peak flow estimated for future development/existing facilities with each alternative at key points within the watershed.

Alternatives I, III and IV have the same percentage peak flow reduction for the Western and Eastern Tributaries at the confluence with Range Wash. However, because Alternatives III and IV include a confluence detention basin, they have a 50 percent greater reduction in peak flow along Range Wash (Sloan Channel), above that for Alternative I. From this comparison, it can

be concluded that inclusion of a confluence detention basin greatly enhances peak flow reduction for Sloan Channel, and diversion of Western Tributary alluvial fan flows has the same effect as a Western Tributary alluvial fan detention basin.

Alternative II provides similar reduction of Sloan Channel peak flows, but further reduces Western Tributary flows at the confluence by a combination of detention and intra-basin diversion to the Eastern Tributary. Whereas Western Tributary peak flows are reduced, no substantial reduction in Eastern Tributary peak flows is obtained.

TABLE III-2

COMPARISON OF 100-YEAR PEAK FLOW (CFS)

Location	Future Development Existing Facilities	Alternative I	II	III	IV
Western Tributary at Confluence	7260	4470	2950	4470	4500
Eastern Tributary at Confluence	3370	860	3100	860	860
Range Wash at Las Vegas Wash	8870	5340	2570	2600	2600

CONCEPTUAL FACILITY COST ESTIMATES

General

Opinions of probable costs for right-of-way and facility construction were prepared for comparing alternatives, and are summarized in Tables III-3, III-4, III-5 and III-6 for alternatives I, II, III and IV, respectively. A contingency of 20 percent of the sum of right-of-way and facility construction cost is included because of the conceptual nature of the facilities. As such, the estimates are opinions of probable cost, subject to changing economic conditions and were developed to allow equal basis comparison of alternatives.

Right-Of-Way Costs

Right-of-way costs are a function of numerous variables, which are not easily defined into monetary values; are best determined on a case-by-case basis with individual property owners;

TABLE III - 3

and vary both in location and time. The facilities proposed for the various alternatives tend to be located in the following general areas:

1. Historical washes and improved drainage channels with existing right-of-way, such as Sloan Channel, from Las Vegas Boulevard North downstream to Las Vegas Wash and the Vandenberg Channel, from Lone Mountain Road to Craig Road.

2. Various United States public and military reservation lands, such as the proposed alluvial fan improvements and the confluence detention basin.

3. Privately held lands within historical drainage paths located adjacent to military reservations, such as the lower Eastern Tributary Detention Basin and the lower reaches of the Eastern Tributary channel improvements near Nellis Air Force Base.

4. Privately held lands within historical drainage paths and developing urban areas, such as the Western Tributary from Craig Road downstream to Las Vegas Boulevard North.

During the conceptual evaluation, officials at Nellis Air Force Base were contacted regarding recent land acquisitions. The privately held lands being acquired by the Air Force were located within the historical drainage path of the Eastern Tributary of Range Wash. Acquisition costs were between $7,000 and $8,000 per acre. On this basis, $8,000 per acre was assumed appropriate for right-of-way costs for privately held lands. For land within the public domain, or on military reservations, costs were assumed at one-half that for private property, or $4,000 per acre.

Right-of-way widths for lined channels and floodways were calculated as the sum of the channel top width and a minimum allowance of 12 feet for maintenance access, rounded up to the next five feet. Right-of-way areas for detention basins were based on an area necessary to contain the basin with a minimum of 12 feet of access around basin limits.

Facility Construction Costs

General

Opinions of probable construction cost were estimated based on generalized unit costs for the major work quantities which could readily be estimated for the type of facility and its geometry relative to the topographic base mapping used. Identification of all components of work was

not possible, but use of slightly higher unit costs for the major components is considered reasonable to include minor work components.

Detention Basins

Using the detention basin volumes estimated during the conceptual hydrologic evaluation, major cost component quantities, such as excavation and embankment were estimated. Each detention basin site was evaluated and a configuration developed based on balanced earthwork quantities. Detention basins were assumed to consist of an earthen embankment with 3:1 side slopes and a minimum top width of 15 feet. Embankments were assumed to be constructed from materials excavated on-site. No specific embankment or foundation treatments for seepage control were considered because of the relative short duration during which flood waters would be detained. Emergency spillways were assumed to be constructed from built-up soil cement core and were sized for the probable maximum flood (PMF) estimated in Chapter II, with a head not greater than six feet. Because of the steep alluvial fan slopes, "in-ground" detention basins, with excavation volumes exceeding storage volume, were not considered cost-effective. In general, for the configurations and sites evaluated, 25 percent to 40 percent of the storage volume was obtained from required excavations.

Channels and Roadway Crossings

Channels were assumed lined with reinforced concrete 6-inches thick and underlain with an 8-inch granular bedding. Quantities of excavation were estimated assuming excavation of the entire channel section (waterway area, structural section and bedding), except along existing channels, such as Sloan Channel. Roadway culvert crossings and modifications to existing crossings were estimated based qualitative lump sum costs provided from local contractors.

Alluvial Fan Dikes and Floodways

Dikes were assumed to be constructed from material excavated for floodways. Dike side slopes were assumed to be 3 horizontal to 1 vertical with the upstream face lined with an 18-inch thick soil cement blanket placed directly on the slope. A five foot lean concrete cutoff along the upstream toe provides erosion and scour protection. The major work items for floodways consist of bulk excavation and construction of gabions for bank stability. Gabions are constructed with a toe-in equal to floodway depth, based on a three foot gabion basket configuration.

Unit Costs

Table III-7 summarizes the unit costs for major work items used in the development of the conceptual facility cost estimates.

TABLE III-7

UNIT COSTS
MAJOR WORK ITEMS

Description	Unit	Unit Cost
Earthwork	Cubic Yard	$ 3.50
Soil Cement	Cubic Yard	$ 50.00
Gabions	Cubic Yard	$ 100.00
Reinforced Concrete		
Slip-form Channel Lining	Cubic Yard	$ 175.00
Structural Formed	Cubic Yard	$ 400.00
Drain Rock	Ton	$ 14.00

CONCEPTUAL ANALYSIS RESULTS

Introduction

The four conceptual alternatives were analyzed to assess their ability to satisfy identified general objectives and relative construction cost. Results of the qualitative analysis and conceptual cost estimates are used to identify two alternatives which are selected for further consideration.

Qualitative Analysis

As a result of detention and conveyance, all alternatives reduce the hazard of flooding on the Western and Eastern Tributaries and below the confluence. Detention facilities located on the alluvial fan, at the apex of the fan, or above areas of significant development all result in decreased discharges and increased control of flood flows. Dikes also reduce flood hazard by controlling flows.

Alternative I has a lesser degree of flow reduction along the Sloan Channel than the other Alternatives because it does not include the confluence detention basin. The higher residual flows are controlled by proposed improvements to the Sloan Channel and downstream crossings. Alternative II includes an intra-basin diversion of flood waters and relies on

establishment of a Beltway alignment and its relationship to proposed improvements. While the Eastern Tributary facilities are sized to handle flows from the Western Tributary, any intra-basin diversion results in the perception of increased hazard due to the increased frequency of flows reaching that portion of the basin.

Alternative IV also increases the perceived hazard to the adjacent drainage basin. The collection and conveyance of water along the dike from the Western Tributary of Range Wash to the North Las Vegas detention basin, located within the Las Vegas Wash drainage basin, is an inter-basin transfer of water. This transfer increases the frequency and duration of flows in the Las Vegas Wash downstream of the detention basin. The basin is sized to mitigate the flooding impacts downstream, however, the prolonged discharge of water from the detention basin introduces additional problems. Increasing the frequency and duration of flooding in the Las Vegas Wash drainage basin, as a result of flows from the Range Wash basin, is a perceived increase in hazard and may result in increased exposure to liability.

The dikes and channel improvements protect property. The dikes confine and control flows resulting in the downstream area being protected from flood hazard. Channel improvements also control and convey flows thereby protecting adjacent properties from flooding.

The Alternative II beltway diversion provides protection downstream of the proposed beltway. The area upstream of the beltway, below the apex dike and diversion channel, is subject to potential flooding from flows generated on the alluvial fan. The flood peaks are not as high as those flows emanating from the canyon above the apex of the fan, however they are large and generally unconfined, consisting of gully flow, overland flow and flow in small channels. These flows are difficult to control without extensive facilities within a development.

All four alternatives address FEMA requirements as they are currently defined, however FEMA requirements for facilities and improvements on alluvial fans are evolving. The overall fan approach is the standard to which FEMA is measuring alternatives. Because of the evolution of alluvial fan technology, there are no guarantees that this approach will be accepted in the future. Under the current FEMA requirements, facilities which are designed to control alluvial fan flows, which consider sedimentation and the associated aggradation and degradation potential, and those which are appropriately maintained, will be processed and appropriate Letters of Map Revision (LOMR) will be issued. FEMA does reserve the right to change criteria and superimpose revised criteria on existing facilities and existing floodplains. Therefore, while we believe the facilities identified in these alternatives meet the current FEMA criteria, no assurances can be given that a LOMR can be obtained at the time of design or construction.

Cost Comparisons

Costs estimates for the facilities identified in each of the alternatives reflect the conceptual level analysis based on preliminary facility sizes. The cost estimates for each alternative are compared and summarized in Table III-8, Summary of Facility Costs. Estimates include the estimated facility construction cost, the estimated right-of-way cost and the total facility cost, for each alternative.

TABLE III-8

SUMMARY OF FACILITY COSTS
(Millions of Dollars)

Alternative		East Tributary	West Tributary	Sloan Channel	Total
I	Facility	$ 12.0	$ 29.0	$ 9.3	
	Land	2.2	2.3	0.0	
	Contingency	2.8	6.3	1.9	
	Total	$ 17.0	$ 38.0	$ 11.0	$ 66.0
II	Facility	$ 30.0	$ 10.0	$ 6.9	
	Land	1.5	1.1	1.0	
	Contingency	6.3	2.2	1.6	
	Total	$ 38.0	$ 13.0	$ 9.5	$ 61.0
III	Facility	$ 12.0	$ 29.0	$ 6.9	
	Land	2.2	2.3	0.8	
	Contingency	2.8	6.3	1.5	
	Total	$ 17.0	$ 38.0	$ 9.2	$ 64.0
IV	Facility	$ 12.0	$ 17.0	$ 6.9	
	Land	2.2	0.9	0.8	
	Contingency	2.8	3.6	1.5	
	Total	$ 17.0	$ 22.0	$ 9.2	$ 48.0

The estimated conceptual level construction costs for Alternatives I, II and III range from $61 to $66 million. Alternative IV has a substantially lower estimated conceptual level construction cost of $48 million. This reduction in estimated cost stems from the diversion of flows from

Range Wash to the North Las Vegas detention basin. The estimate does not include any modifications to the detention basin nor does it include any channel improvement costs downstream of the basin outlet.

Selected Alternatives

Subsequent to a review of the findings of the conceptual evaluation with the Project Sponsors, Alternatives III and IV were selected for further evaluation and preliminary design. These alternatives feature many common elements including, confluence detention, limited improvements to Sloan Channel, improvements along the Eastern Tributary of Range Wash from the alluvial fan downstream to the confluence, and improvements from the Union Pacific Railroad tracks to the confluence along the Western Tributary. The alternatives differ in their handling of Western Tributary alluvial fan flows. Alternative III provides dikes and a floodway conveying flows to a detention basin located on the alluvial fan and a channelized outflow downstream. Alternative IV consists of the diversion of Western Tributary flows across the alluvial fan to the existing North Las Vegas detention basin.

During the review process, the importance of a confluence detention basin to the facility plan became evident. Also, since the lower Eastern Tributary Detention Basin (facility E-P1) is in close proximity to the confluence detention basin and only reduces peak flows for a short reach downstream to the confluence detention basin, project sponsors suggested that only a single confluence detention basin be considered for preliminary design investigations. It was concluded, after further evaluation, that such a plan was feasible and advantageous because of the economics of scale related to cost of a single, large detention basin as opposed to cost of two, moderate sized detention basins.

Subsequent to the identification of these two alternatives, Nellis Air Force Base identified that the confluence detention basin site is an abandoned landfill which may contain hazardous materials. The Air Force is currently evaluating this as a potential Superfund cleanup site. It was determined that an alternative detention basin site would be preferable, if the flood control requirements could be satisfied. After consultation, review and evaluation, an alternative site was identified to the east of Nellis Air Force Base, adjacent to the existing golf course. This site is located on the Eastern Tributary of Range Wash. Moving the detention basin to this location requires a channel across the Nellis Air Force Base golf course to convey Western Tributary flows to the proposed detention basin site. This golf course channel requires integration into the existing golf course and will be earth or grass lined. The alternative detention basin site further justifies the elimination of detention basin E-P1. This is accomplished by enlarging the

size of the previously proposed confluence detention to utilize the additional storage volume available at the newly identified site. This change is include in the evaluation and preliminary design of the two selected alternatives.

The selection of Alternatives III and IV is based largely on the estimated construction cost savings resulting from detention basin construction at the confluence versus the construction of the necessary channel improvements along the Sloan Channel. The difference in cost between these two approaches has been estimated at approximately $2 million. The detention basin also provides an additional benefit in that the construction of the basin along with the golf course channel alone immediate benefits to downstream properties. Because the these facilities are located at the natural low point, extensive upstream facilities are not required to collect the flow and downstream improvements are minimized because of flow reduction.

Alternative II, the Beltway Alignment Alternative, was not selected because of the uncertainty regarding the final beltway alignment and the relationship of the beltway with any proposed drainage improvements. The construction of the beltway diversion dike is a considerable expenditure. The reconstruction of this dike to accommodate an altered beltway alignment would require considerable capital expenditures and was deemed ill-advised at this time.

IV - PRELIMINARY DESIGN

INTRODUCTION

Two of the alternatives evaluated during the conceptual analysis phase of this study were selected for preliminary design. The selection for preliminary design was based on estimated construction cost and non-quantifiable considerations such as flood hazard reduction, ease of implementation, and compatibility with future development plans within the community. The two selected alternatives are Alternative III - the Master Plan with Confluence Detention Alternative, and Alternative IV - the Diversion to North Las Vegas Detention Basin Alternative.

The purpose of the preliminary design is to identify general components of the selected alternatives such as types and sizes of facilities and their approximate location. The sizing of facilities is based on a refinement of the hydrologic model and hydraulic analysis. Design of detention facilities includes estimates of required storage volume, embankment height and spillway geometry. Channel and floodway preliminary design includes slope, geometry and lining type. Street crossings include identification of required culvert sizes or bridge spans. Preliminary horizontal alignments of channel and crossing facilities are identified schematically on the drawings developed. Vertical elevations are identified using the available topographic information. Utilizing the alignments and grades established by this design, utility conflicts are identified and reconciled to the extent possible. Right-of-way acquisition limits are estimated and included. The previously prepared cost estimates are refined to reflect the preliminary design effort.

The preliminary designs for Alternative III and Alternative IV are depicted on the drawings presented as Appendix A of the report. This preliminary design is conceptual in nature and lacks significant detail because no detailed topography was developed for this study. USGS 7-1/2 minute quadrangle maps, enlarged to a scale of 1" = 500', were used as base mapping. The 20-foot contour interval is the basis for most vertical information presented on the plans. This information is supplemented with record drawings of specific improvements, where available. Using the preliminary designs and alignments established during this study, more site specific surveying can be obtained for final design of facilities along the selected alignment.

No extensive utility location, surveying, or potholing program was performed. Utility owners were notified and utility maps made available were consolidated during the study. The utilities

identified on the plans are those reported by the various utility owners. This information was used during the conceptual evaluation and the preliminary design to reconcile potential utility conflicts. Subsequent field surveys for design should include more site specific utility location to allow for the detailed reconciliation of possible conflicts.

The identification of precise horizontal and vertical alignments for these improvements is not possible since no site specific mapping was performed for this project. The horizontal alignments depicted on the plans are related to physical features identified through field observation and from the available mapping. Alignments are generally identified by their relation to existing facilities such as road crossings or channels or by their proximity to existing rights-of-way. Horizontal information provided on the plans is provided to identify hydraulic constraints (for example, curve radius data). Specific horizontal alignments will be established during final design.

Vertical alignments are based on the 20-foot contour interval presented on the USGS quadrangle maps. In some cases, the existing crossings were identified on record drawings with elevations called out using the USGS datum. In these cases, the record elevations are used. All other elevations and grades identified on the plans are approximate and reflect the accuracy of the available topographic mapping.

The cost estimates prepared during this study reflect the preliminary nature of the project. No detailed structural analysis or design was performed for the facilities nor was a detailed estimate of earthwork prepared. The costs represent estimates consistent with the level of detail of the study and the topographic mapping available. Appropriate contingencies have been included in the cost estimates to reflect the lack of detail of the available information.

ALTERNATIVE DESCRIPTION

The two alternatives selected for preliminary design are Alternative III, The Master Plan with Confluence Detention Alternative, and Alternative IV, The Diversion to the North Las Vegas Detention Basin Alternative. Both alternatives were selected because of their relative low cost and because they satisfy the primary objectives of flood hazard reduction and development potential enhancement. The major elements of Alternative III include control of flows on the alluvial fan using a system of dikes and floodways and the incorporation of detention at the confluence of the Eastern and Western Tributaries of Range Wash. The principal element of

Alternative IV is the diversion of alluvial fan flows from the Western Tributary to the existing North Las Vegas Detention Basin.

Alternative III

Alternative III facilities are depicted on Sheets 3 thru 19 of the drawings included as Appendix A. The facilities consist of collector dikes on the Western Tributary of Range Wash with a floodway conveying flows south to a detention basin located above proposed development areas on the alluvial fan. From the detention basin, an outlet channel conveys flows downstream to the Union Pacific Railroad tracks, then along the tracks to a crossing near the interchange of Lamb Boulevard and Interstate 15. The channel then turns to the south, crossing the Interstate and continues southeast to a crossing of Las Vegas Boulevard North near Marion Drive. From the Las Vegas Boulevard North crossing, the channel flows southeasterly, eventually traversing the Nellis Air Force Base golf course and discharging into the confluence detention basin.

Flows from the East Range Wash drainage basin are collected by dikes on the alluvial fan and conveyed in a stabilized floodway south to a crossing of the Union Pacific Railroad tracks and then in a stabilized channel to a detention basin near I-15. Flow is then conveyed in a lined channel extending south along an existing railroad spur, beneath Interstate 15 to Las Vegas Boulevard North, and along the northeast boundary of Nellis Air Force Base to Nellis Air Force Base Area 2. The channel turns to the southwest and extends along the southeastern boundary of Nellis Air Force Base into the confluence detention basin.

The confluence detention basin is located east of the Nellis Air Force Base golf course and stores flow from the Eastern Tributary of Range Wash as well as those from the Western Tributary which have been conveyed across the golf course. The detention basin discharges flows into a stabilized channel located along the eastern boundary of the Nellis Air Force Base landfill and ultimately into Sloan Channel. Sloan Channel conveys flows south to their ultimate outfall in Las Vegas Wash. Portions of the Sloan Channel are adequate for the conveyance of the 100-year flood and are not identified for improvement. Unlined portions of Sloan Channel are identified for improvement to convey clear water discharges from the Confluence Detention Basin.

Alternative IV

Alternative IV, the Diversion to the North Las Vegas Detention Basin Alternative, is depicted on Sheets 3 through 7, 14 through 18, and 20 through 22 of the drawings included as Appendix A. This alternative consists of many elements already identified as part of Alternative III.

Specifically, facilities downstream of Interstate 15 on the Western Tributary of Range Wash, all of the Eastern Tributary of Range Wash and the entire Sloan Channel improvements are the same for both Alternatives III and IV.

The differences between Alternatives III and IV are limited to the means of handling alluvial fan flows on the Western Tributary. Alternative IV proposes to divert alluvial fan flows (at a location near the Alternative III detention basin) to the west to the existing North Las Vegas detention basin. Because of this diversion, no additional facilities are required on the fan north of the Union Pacific Railroad tracks. The proposed Alternative IV facilities are shown on the drawing included as Appendix A. For simplicity, the components which are common to both Alternatives III and IV are not repeated, rather, references are made to the appropriate drawings depicting Alternative III improvements.

Golf Course Channel Evaluation

The location of the proposed confluence detention basin (Basin R-M) at the eastern edge of the Nellis Air Force Base golf course requires the construction of a conveyance system to direct Western Tributary flows across the golf course. Both Alternatives III and IV include this channel. The City of North Las Vegas and the Clark County Regional Flood Control District recognized the significance of this conveyance and its possible impact on the operation of the golf course. As a result, they requested that a more detailed evaluation be performed to minimize disruption to the golf course and ot properly integrate the channel into the course.

Three alternatives were evaluated and discussed with the Nellis Air Force Base leadership. Their comments were received and incorporated into Alternatives III and IV.

The first alternative evaluated requires the shifting of one hole to allow the channel to follow the northern perimeter road. It also includes box culvert crossings of two fairways as well as two culvert crossings at the perimeter road.

Alternative two does not require the relocation of any golf holes, however, the channel crosses two fairways as an open ditch. One crossing is a trapezoidal section with 3:1 side slopes and the other is a trapezoidal section with very flat, 8:1 to 12:1, side slopes. Once again, crossings of the perimeter road are required in two locations.

The third alternative requires the relocation of two golf holes but only one crossing of a fairway. The channel passes between the relocated holes and crosses the single fairway using the flat side slope trapezoidal channel section. Two crossings of the perimeter road are required.

An evaluation of these three alternatives was performed. Of greatest concern to the City and CCRFCD were the flood carrying capacity, the cost and the maintenance issues associated with the proposed facilities. The Air Force Base was primarily concerned with the impacts on their property and with the potential for disruption to golf course use. To address these concerns, Boyle evaluated the hydraulics and was able to size facilities such that flood control objectives were not compromised. A cost estimate was prepared which identified the cost of the three alternatives. Maintenance access was provided to all facilities and slopes were proposed to minimize access problems and expedite cleaning, mowing and repair. To alleviate the concerns regarding disruption to use of the golf course, a detailed construction schedule was provided for each alternative. This resulted in the identification of construction timetables which minimized the duration of disruptive activities.

After considerable discussion and modification, agreement with the Air Force was reached on a revised version of Alternative 2. This alternative has been included in the facility plan and is shown on Sheet 19 of the included drawings. Changes to the original Alternative 2 include the modification of the channel alignment entering the golf course. This modification requires an additional road crossing but provides a hydraulically efficient alignment. Architectural stone bridges have been requested to minimize the visual impact of required pedestrian and maintenance crossings of the channels where they cross fairways. The Air Force Base also requested that the flat sloped channel crossing of the fairway be modified to the steeper geometry to minimize disruption to the golf hole.

Specific details of the various amenities associated with improvements to the golf course will be identified at the time of final design of the improvements. The Air Force Base has requested other elements such as continued access to their well and assurances that their existing utility systems will not be disrupted. These requests will be addressed during final design but are beyond the level of detail required for this facility planning study. When final design is initiated, these facilities will be formally incorporated.

HYDROLOGIC EVALUATION

Hydrologic Models

The proposed facilities for each alterative selected were superimposed on the watershed and the subbasin delineation utilized for the existing conditions model was adjusted to reflect the proposed facilities. Basin and routing parameters were also adjusted to reflect addition of the

proposed facilities. Subbasin and model nodes are depicted in Figures IV-1 and IV-2, for Alternatives III and IV, respectively.

Based on the conceptual hydrologic analysis results, stage-storage-discharge relationships were developed for each detention basin and included in the models. Initial simulation runs were made and adjustments made in detention basin volumes and discharge relationships. This was done to size detention basins such that peak discharges in outlet channel reaches were approximately the same for an intense storm below the detention basin as for the basin discharge, and to "fine tune" the conceptual hydrologic analysis.

Results

Once the base models were prepared, analyses were made simulating precipitation over portions of the watershed to estimate critical discharges for facility design. Storm descriptions and designations simulated for each alternative are summarized in Table IV-1 and schematically depicted in Figure IV-3.

GENERAL NOTES

1. BASE MAPPING IS COMPOSED FROM PHOTOGRAPHIC ENLARGEMENTS OF THE FOLLOWING USGS 7.5 MINUTE QUADRANGLES:
   LAS VEGAS NE (1967) (PHOTO REVISED 1984)
   FRENCHMAN MTN (1970) (PHOTO REVISED 1983)
   VALLEY (1974)
   APEX
2. FACILITIES ARE DEPICTED FOR PLANNING PURPOSES ONLY, NOT FOR CONSTRUCTION. FINAL ALIGNMENT AND DIMENSIONS ARE CONTINGENT ON FINAL DESIGN.
3. SLOPES ARE NOTED IN FT/FT.
4. IDENTIFIED RIGHT-OF-WAY REQUIREMENTS ARE BASED ON CLARK COUNTY ASSESSORS MAPS OBTAINED IN APRIL 1989.
5. EXISTING UTILITIES AND DRAINAGE FACILITIES ARE BASED ON INFORMATION OBTAINED FROM PROJECT SPONSORS AND DO NOT REFLECT ACTUAL FIELD SURVEYS.
6. *FOR CLARITY, CHANNEL TRANSITIONS ARE NOT SHOWN.* DESIGN OF TRANSITIONS WILL BE BASED ON DETAILED HYDRAULIC EVALUATIONS PERFORMED DURING FINAL DESIGN.

CHAPTER I

INTRODUCTION

I - INTRODUCTION

GENERAL INTRODUCTION

The evaluation and preliminary design of drainage facilities within the Eastern and Western Tributaries of Range Wash upstream of the Sloan Channel, in the Las Vegas Valley area of Nevada, was performed under the terms of an agreement executed on January 18, 1989 between the City of North Las Vegas, Nevada and Boyle Engineering Corporation.

The purpose of the project is to evaluate and develop preliminary designs for drainage facilities within the Eastern and Western Tributaries of Range Wash. The effort includes a review of previously developed studies, updating and refining existing hydrologic models, development and evaluation of alternative flood control facilities, conceptual design of selected flood control facilities within the Western and Eastern Tributaries of Range Wash, and the preparation of a report summarizing the effort.

PROJECT LOCATION

The Range Wash drainage basin is located in the northeast portion of the Las Vegas Valley (Figure I-1). The study area boundary is bounded on the north and east by the Las Vegas Mountain Range and extends into the Desert National Wildlife Range.

The basin lies entirely within Clark County, Nevada and includes portions of the City of North Las Vegas, Nellis Air Force Base, and portions of unincorporated Clark County. The entire drainage area is contained within the boundaries of the Clark County Regional Flood Control District.

The Range Wash Drainage Basin is a tributary to Las Vegas Wash. Flows from Range Wash enter Las Vegas Wash adjacent to the Sunrise Station Power Plant near the intersection of Vegas Valley Drive and Hollywood Boulevard. The mainstem of Range Wash extends north from this location approximately five miles along the Sloan Channel to the southern limit of Nellis Air Force Base at the confluence of the Western Tributary of Range Wash with the Eastern Tributary of Range Wash.

VICINITY MAP

NOT TO SCALE

FIGURE I-1

The Western Tributary of Range Wash extends along the western boundary of Nellis Air Force, then northwesterly crossing Las Vegas Boulevard North, Lamb Boulevard, and Craig Road, and through the Vandenberg Channel and a crossing of I-15. Upstream of I-15 and the parallel Union Pacific Railroad track, the channel is fairly poorly defined with numerous minor channels distributed across the alluvial fan. Upstream of the alluvial fan area, in the Las Vegas Mountain Range, channels are well defined.

The Eastern Tributary of Range Wash extends around the eastern boundary of Nellis Air Force to a point near the intersection of O'Dannon Road and Forrestal Boulevard between the main base area and Area 2. Here, two fairly distinct branches join. The easterly branch extends northeasterly into the Las Vegas Dunes Recreation Lands area. The westerly branch collects flows from an area to the north and east of the Western Tributary alluvial fan.

The basin can be characterized by three distinct land types: mountainous; alluvial fan, and; urban developed. The mountainous regions of the watershed are steep rocky areas with limited vegetation and high runoff potential. Areas on the alluvial fan are characterized by alluvial deposits and numerous incised channels of limited capacity. Runoff from this area is relatively low however, hydraulic conditions are such that the route of flood flows is difficult to predict. The highly developed area, downstream of I-15, is generally characterized by existing residential and commercial developments and Nellis Air Force Base, with rapid development and construction of additional commercial and residential developments. Runoff from this area is rapid and high due to the large amount of impervious surface found in the area.

PROJECT SCOPE

The drainage planning study for the Western and Eastern Tributaries of Range Wash involves the preparation of conceptual designs for drainage improvements along the two tributaries of Range Wash. The defined scope of work includes the five following principal components:

- Data Collection and Project Coordination;
- Hydrologic Analysis;
- Alternative Development and Evaluation;

- Conceptual Design of Drainage Improvements, and;

- Report Preparation

Data collection and project coordination were among the first tasks performed for the project and continued throughout the duration of the project. This effort involved obtaining and reviewing past hydrologic studies of the watershed, alternative flood control measures previously proposed within the watershed, and final design drawings of storm drainage facilities. The effort also included the collection and review of utility plans, land-use plans and the identification of regulatory requirements imposed on potential improvements within the watershed. An initial meeting and on-going project coordination meetings were held to facilitate the collection of data, to review project progress, and to discuss project results. These meetings included representatives from the City of North Las Vegas, the Clark County Regional Flood Control District, Clark County Public Works Department, Nellis Air Force Base, and the Cities of Henderson and Las Vegas. In addition to those in attendance at the meetings, coordination and communication with other agencies such as the Federal Emergency Management Agency and the U.S. Army Corps of Engineers was also established and maintained throughout the project duration.

A hydrologic analysis was performed for the Range Wash watershed. This analysis included an evaluation of the hydrologic response of the Western and Eastern Tributaries of Range Wash for both the existing and future drainage basin conditions. A hydrologic computer model was utilized to simulate the response of the watershed to design rain storms. The model was calibrated to the computed probability results presented by the U.S. Army Corps of Engineers in their Feasibility Study. A sediment yield analysis was also performed to estimate probable sediment volumes reaching the proposed facilities.

The results of the hydrologic analysis were used to establish design discharges for proposed facilities within the watershed. The model was also used to evaluate the impacts of proposed facilities on downstream flows and to provide additional information for the sizing of downstream facilities.

Four conceptual alternative facilities were identified for the control of flooding within the Range Wash watershed. These facilities were developed in conjunction with the City of North Las Vegas, the Clark County Regional Flood Control District, and the other agencies identified and

involved in the project. These alternatives were selected to reconcile the identified technical, economic, political and aesthetic considerations within the watershed.

The evaluation of the four conceptual alternatives included locating, sizing and cost estimating the various component facilities. Simplifying assumptions were made to identify the most attractive alternatives for further study.

Two of the four conceptual alternatives were selected for further refinement. This refinement effort included a more detailed hydrologic impact assessment, more site-specific facility sizing, more extensive hydraulic analysis, and more detailed cost estimate preparation. The conceptual design also included sizing of hydraulic structures including bridge and street crossings, a determination of the hydraulic grade line through the proposed facilities, and a determination of a conceptual vertical alignment of the proposed facilities.

In addition to the conceptual design of the facilities, estimates of probable right-of-way requirements for the alternatives were included. This information, along with the general details of the conceptual design, was presented on plan and profile sheets.

This report summarizes the project work. A discussion of the work performed is included along with a brief discussion of the advantages and/or disadvantages of the alternatives, and a presentation of the plan and profile drawings. Included in the report is a phasing plan to facilitate the implementation of the Plan.

EXISTING DATA

Data from several sources was collected which might effect the feasibility and economics of the various alternative facilities. Sources for the data included governmental agencies such as the City of North Las Vegas, Clark County Public Works Department, Clark County Regional Flood Control District, and Clark County Comprehensive Planning. Other governmental agencies were contacted to identify and collect additional information. These agencies included Nellis Air Force Base, the Federal Emergency Management Agency, and the U.S. Army Corps of Engineers. Utility information was also collected from the various utility companies within the watershed including the Clark County Sanitation District, Nevada Power Company, Southwest Gas Corporation, and telephone and cable TV companies. The information obtained from the various sources was important in identifying the extent of existing facilities within the watershed. Existing drainage improvements were also identified. These included existing channels, street crossings and existing detention facilities which might be utilized for alternative plans.

Land uses within the watershed were perhaps the most important constraint to proposed facilities. Land-use information identified both the character and type of existing development, as well as proposed development locations and extent. Existing land uses within the watershed were identified using combinations of available mapping, area photographs, and field reconnaissance. This information was supplemented by existing hydrologic and planning studies available for the basin. Future land-use information was obtained from the City of Las Vegas Land-Use Plan, Clark County Comprehensive Planning, and the previous studies. This information was compiled and presented to the City of North Las Vegas and the other interested agencies for review and comment. Subsequent to the initial collection effort, the City of North Las Vegas provided amended land-use plans which resulted in a slight modification of development limits and facility sites. This information was utilized to identify feasible alignments and facility sites.

EXISTING BASIN DESCRIPTION

The Range Wash drainage basin is located in the northeast portion of the Las Vegas Valley. The watershed drains a western tributary and an eastern tributary. The Range Wash basin is tributary to Las Vegas Wash with its outfall near the Sunrise Station Power Plant. Flow in the basin is generally from north to south. The Western Tributary watershed headwaters are in the uplands of the Las Vegas Mountain Range. Runoff leaving the Las Vegas Mountain Range flows across an alluvial fan in a southerly direction and is intercepted by a Union Pacific Railroad line and Interstate 15. After crossing these roads, flow is in a general southeasterly direction to the southern portion of Nellis Air Force Base where it joins flows from the Eastern Tributary. Eastern tributary flows begin in the lower portions of the Las Vegas Mountain Range in the Las Vegas Dunes Recreational Lands area just to the northeast of the intersection of Interstate 15 with Las Vegas Boulevard north. Flow from this area is generally to the south or southwest and passes along the eastern border of the Nellis Air Force Base main base area. Here flows combine and flow in a southwesterly direction to the southern portion of Nellis Air Force Base where they join with Western Tributary flows. Combined flows then proceed southward along the Sloan Channel to the ultimate outfall into Las Vegas Wash.

The watershed consists of three distinct regions: the northern and eastern mountainous areas; the central alluvial fan, and; the downstream developed basin. The mountainous areas are rugged and steep with nominal vegetation and high runoff potential. The alluvial fan area is characterized by numerous small incised channels across the steep alluvial fan areas. The

downstream developed areas of the watershed are combinations of residential and commercial developments.

At the transition from the alluvial fan areas to the downstream developed areas lies Nellis Air Force Base. This property is affected by flows from both the Western Tributary and the Eastern Tributary of Range Wash. Nellis is somewhat protected by the presence of Interstate 15, the Union Pacific Railroad, and Las Vegas Boulevard North. Crossings of these streets or railroads concentrate flows and subject the Air Force Base to concentrated flows.

Existing drainage facilities within the Range Wash basin are relatively limited. Sloan Channel improvements are designed and partially constructed. This affords some limited protection to downstream properties. The Vandenberg Channel, immediately downstream of I-15, is another improved section of the channel. Nellis Air Force Base has completed improvements to several segments of the channel in and around the Air Force Base for the protection of Air Force property. Beyond these channel structures, the improvements are generally limited to street and railroad crossing structures which are frequently inadequate to convey the full 100-year flows. The Clark County Regional Flood Control District Master Plan has identified several facilities to control runoff from the Western and Eastern tributaries of Range Wash. These facilities are incorporated into the alternatives evaluated. The facilities proposed in the Regional Flood Control District Master Plan have not been designed or constructed.

CHAPTER II

HYDROLOGY

II - HYDROLOGY

INTRODUCTION

Hydrologic analyses were performed for the Western and Eastern Tributaries of Range Wash upstream of Las Vegas Wash. The purpose of these analyses was to update past hydrologic studies and to develop detailed hydrology for the evaluation and of sizing facilities in the Range Wash watershed.

The Clark County Regional Flood Control District Master Plan developed hydrology for the entire Clark County area including Range Wash. This effort, while comprehensive in scope, was predicated on a number of generalized regional assumptions. These assumptions render the flows developed for individual watersheds inadequate when evaluating site specific facilities.

The U.S. Army Corps of Engineers developed a computer model for the Las Vegas Valley which was based on the Master Plan model. This model refined some of the regional assumptions used in the Master Plan and is more useful in evaluating site specific facilities. The Corp of Engineers model did not provide a sufficient level of discretization, nor did it utilize sufficient detail in representing rainfall losses, to be used without modification in this study.

The following sections present Boyle's approach in the development of a hydrologic model for the Western and Eastern Tributaries of Range Wash including methodologies, assumptions and results of the analyses. The adopted methodologies are based on the Hydrologic Memorandum submitted on March 27, 1989.

MODELING APPROACH
