TSDN - Flood Insurance Study

Upper Las Vegas Wash
City of Las Vegas, City of North Las Vegas, Unincorporated Areas of Clark County
EMW - 95 - C - 4840

Introduction to Volume 4

This volume of the TSDN contains engineering analyses performed during the FIS, including hydrologic and hydraulic analyses. The study was completed for two cases due to uncertainty regarding the performance of the North Las Vegas Detention Basin Diversion Dike during a major flood event. This volume contains the analyses for the '**Without North Las Vegas Detention Basin Diversion Dike**' case. Volume 3 contains similar analyses for the "With North Las Vegas Detention Basin Diversion Dike'. A discussion of the evaluation of the diversion dike and other flood control structures in the study area is included in Volume 2.

Addendum to Hydrology Memorandum
Upper Las Vegas Wash
for
'Without North Las Vegas Detention Basin Diversion Dike' Case

The attached hydrology memorandum was prepared for the Upper Las Vegas Wash assuming the diversion dike at the North Las Vegas Detention Basin would remain in place during major flood events. The analysis for the 'Without North Las Vegas Detention Basin Diversion Dike' Case differs from the "with" case in two respects:

- The Diversion Dike is assumed to fail when overtopped. Overtopping was computed to occur near the peak of the 100-year Interbasin Storm (see Volume 2 of the TSDN). Therefore, the 100-year peak downstream of the basin was taken to be equal to the 100-year peak from the Interbasin Storm. The 500-year peak flow from the Spring Mountain Storm is higher than the Interbasin Storm, and this flow was used in computing 500 - year water surfaces downstream of the dike.

- The 100-year flood boundary immediately upstream of the dike was based on the Interbasin Storm 100-year peak flow, and is thus the same as for the 'With' case. No 500-year flooding limits are shown in this area because the 500 - year flow is assumed to pass through the opening of the failed diversion dike. Without the dike in place, the computed water surface elevations for the 500-year flow in this area are below the computed 100-year water surface elevations with the dike in place prior to overtopping.

- The pool elevation for the North Las Vegas Detention Basin is computed for the 100-year case using the Spring Mountain Storm, which has a lower peak discharge than the Interbasin Storm, but higher volume. The 500 - year pool elevation is computed using a 500 - year storm on the Range Wash. The Range Wash 500 - year precipitation was extrapolated from the precipitation data in existing HEC-1 models developed by Post, Buckley, Schuh, & Jernigan (1996), and based on the HEC-1 models developed by James M. Montgomery (1991) for the Clark County Regional Flood Control District. The methods used for extrapolating the precipitation data for the Range Wash Storm were similar to those described in the Hydrology Memorandum for extrapolating data for the Interbasin and Spring Mountain Storms.

Peak discharges for the 10- and 50- year events remain unchanged in the 'Without' case, as the dike is assumed to remain in place for these events. The resulting peak discharges for use in the flood insurance study are listed in the table below.

Table 1 - Flood Insurance Study Peak Discharges
Upper Las Vegas Wash
Without North Las Vegas Detention Basin Diversion Dike

HYDROLOGY MEMORANDUM
UPPER LAS VEGAS WASH

1. Hydrology

1.1 Study Approach

The Upper Las Vegas Wash is an ephemeral desert stream draining a basin area of approximately 720 square miles originating in the Spring and Sheep Mountains upstream of the City of Las Vegas. Peak flows from the majority of the basin are controlled by two major detention basins: the North Las Vegas Detention Basin constructed in 1984 and the Upper Las Vegas Wash Detention Basin constructed in 1993. The tributary area to the North Las Vegas Detention Basin was increased by 48 square miles with construction of the Range Wash Diversion Dike in 1994. Figure 1-1 shows basin boundaries above the major flood control structures.

Previous hydrology studies for flood control facility design and for determining regulated flood discharges include work by the U.S. Army Corps of Engineers (1988), James M. Montgomery (1991), Boyle Engineering Corporation (1991) and by Black & Veatch (1993).

The approach and objectives for the current hydrologic analysis are to assess the adequacy of the previous analyses, and to update and re-run previously-developed Flood Insurance Study HEC-1 models as necessary to reflect existing flood control facilities.

1.2 Previous Hydrology Studies

The hydrology of the Upper Las Vegas Wash has been studied in numerous previous reports. Recent studies leading to the development of HEC-1 models adopted for use in the present work are listed below.

- U.S. Army Corps of Engineers (COE), South Pacific Division, "Hydrological Documentation for Feasibility Study, Las Vegas Wash and Tributaries, Clark County, Nevada," draft dated April 1988. That study provided a regional analysis of flood frequency data, including 20 years of peak flow data for USGS Gage 09419650, Las Vegas Wash at North Las Vegas. The Las Vegas Wash at this location reflects flows from the Upper Las Vegas Wash channel. The COE developed a computed probability 100-year regional flood frequency curve, reproduced here as Figure 1-2.

- Black & Veatch (B&V), "Flood Control Facilities Plan for the Northern Las Vegas Wash," August 1989. That study included the development of HEC-1 models with various storm centerings for the Upper Las Vegas Wash basin.

- Boyle Engineering Corporation, "Western and Eastern Tributaries of Range Wash Flood

Control Facility Plan," prepared for City of North Las Vegas, June 1991. That study included HEC-1 modeling and led to construction of the West Range Wash Diversion Dike which now diverts flow from 48 square miles of the Range Wash basin into the North Las Vegas Detention Basin.

- B&V, "Predesign Report for the Upper Las Vegas Wash Detention Basin," prepared for City of North Las Vegas, March 1991. That study included HEC-1 modeling of the upper portion of the Las Vegas Wash basin, and led to construction of the Upper Las Vegas Wash Detention Basin and an accompanying interception berm/channel extending to the west from that facility.

- James M. Montgomery (JMM), "Clark County Regional Flood Control District Las Vegas Valley Flood Insurance Study Hydrology Report," September 1991 (Adopted November 14, 1991). HEC-1 models for that study were based on the HEC-1 models developed by B&V (above). Model calibration was attained by matching previous COE and B&V discharges in an initial set of model runs which did not include proposed flood control facilities The proposed facilities were then introduced to the models to generate Flood Insurance Study (FIS) flows.

- B&V, "North Las Vegas Detention Basin Outlet Modification Report," prepared for City of North Las Vegas, August 25 1993. That report included HEC-1 modeling of 6 storm centerings to examine impacts of the Upper Las Vegas Wash Detention Basin and West Range Wash Diversion Dike on outflows from the North Las Vegas Detention Basin. This work led to modification of the North Las Vegas Detention Basin outlet structure by closing two of the five original outlet pipes.

A review of peak flow data through 1993 for the USGS Las Vegas Wash gage (Gage 09419650, Las Vegas Wash at North Las Vegas) found that no significant flood events have occurred since the COE's 1988 analysis that would substantially change the results of that assessment. The lack of additional significant events in the Las Vegas Wash would tend to lower the COE-estimated 100-year discharge for that station, but the COE's adopted regional analysis curve (Figure 1-2) already results in a slightly lower 100-year discharge estimate for that station than frequency analysis of the individual station gage records. The COE's regional analysis for 100-year peak discharge versus drainage area therefore continues to be a reasonable method for estimating unregulated peak flows for the Upper Las Vegas Wash basin.

Existing HEC-1 models of the Upper Las Vegas Wash were "calibrated" to the COE regional analysis curve, and should provide a reasonable estimate of unregulated peak flows. However, it should be noted that there was no calibration to the shape or volume of runoff hydrographs, apparently due to a lack of data for such calibration. The accuracy of the shape and volume of simulated runoff hydrographs, which are important to the performance of detention facilities, is therefore unknown. Hydrographs simulated by the existing HEC-1 models assume a hydrograph shape defined by the SCS unitgraph approach.

The previous analyses considered numerous separate storm centerings over the basin to identify storm configurations which produced the highest peak flows at various locations in the basin. Multiple storm centerings were required because peak flows in the region result from cloudburst events having areas less than 200 square miles and that only cover a portion of the entire Upper Las Vegas Wash basin. For the present work, we have accepted the findings of the previous B&V (1993) and JMM (1991) studies as to which theoretical design storms are most critical for determining FIS discharges:

- The "Spring Mountain Storm" previously used by both JMM and B&V produces the highest uncontrolled peak inflows to the Upper Las Vegas Wash detention basin, as well as the highest peak outflows from both the Upper and North Las Vegas Wash detention basins. This storm was compared to the "Sheep Mountain Storm" by B&V (1993) and determined to be the critical storm for peak inflows and volumes to the North Las Vegas Detention Basin during design of outlet modifications. The Spring Mountain storm has been modeled as a 136.34 sq. mi. storm centered over the Spring Mountain Range. Spring Mountain storm HEC-1 models had previously been developed by JMM (1991) with 10-, 50-, and 100-year rainfall amounts. The Spring Mountain storm simulates a 100-year (uncontrolled) peak flow of 14,737 cfs into the Upper Las Vegas Wash detention basin. Considering the detention basin's total tributary area of approximately 516 sq. mi., the HEC-1 result, is consistent with the COE's regional analysis curve (Figure 1-2).

- The "Interbasin Storm" previously used by B&V produces the highest 100-year peak inflow to the North Las Vegas detention basin. The Interbasin storm has been modeled as a 54.37 sq. mi. storm covering the North Las Vegas Wash tributary area between the Upper and North Las Vegas Wash detention basins. A single Interbasin storm model had been developed by B&V (1993) to represent 100-year storm conditions only. The Interbasin storm simulates a 100-year (uncontrolled) peak flow of 8,537 cfs from the 54.37 sq. mi. basin and is consistent with the COE's regional analysis curve (Figure 1-2).

- An unnamed storm covering the entire 48.16 sq. mi. tributary area to the West Range Wash diversion dike produces the highest peak flows for the West Range Wash diversion dike. A HEC-1 model for this storm had previously been developed by Boyle (1991) for 100-year storm conditions only. This storm simulates a 100-year (uncontrolled) peak flow of 6,584 cfs from the 48.16 sq. mi. basin, which is about 13% lower than the 100-year peak flow indicated from the COE's regional analysis curve (Figure 1-2).

For purposes of the present work, the previously-developed Spring Mountain 10-, 50-, and 100-year HEC-1 models were updated to reflect the existing flood control facilities, and additional Interbasin storm models were developed to represent 10- and 50-year rainfall amounts. HEC-1 models representing 500-year rainfall amounts were developed for both the Spring Mountain and Interbasin storms.

No modifications were made to the HEC-1 model representing West Range Wash diversion dike flows, as FIS discharges for floodplain mapping were not required for this location. If required for other purposes, approximate 10- through 500-year values for West Range Wash diversion dike flows could be estimated by multiplying Interbasin storm values by 0.89, which is the ratio of Interbasin storm to West Range Wash diversion dike basin areas.

1.3 Modifications to Existing HEC-1 models.

HEC-1 models developed by JMM (1991) for the Spring Mountain storm and by B&V (1993) for the Interbasin storm were used as the basis for hydrologic modeling in the present study. No changes were made to any of the previously-defined runoff or channel routing parameters including basin areas, curve numbers, loss rates, channel geometry, and channel routing coefficients. Furthermore, no changes were made to subbasin rainfall amounts for 10- through 100-year return periods, precipitation multipliers, or depth-area correction factors, all of which appeared to be consistent with values recommended by the Clark County Regional Flood Control District Hydrologic Criteria and Drainage Design Manual (1990).

Spring Mountain Storm Files

Spring Mountain 10-, 50-, and 100-year storm HEC-1 files for the present study are based on HEC-1 files prepared by JMM (1991) for the previous FIS hydrology study. Modifications to the JMM files consisted of updating the detention basin characteristics for existing conditions as follows:

- Stage-storage and stage-discharge relationships for the Upper Las Vegas Wash detention basin were updated to reflect as-built conditions. The 1991 JMM model had been based on a preliminary detention basin design which was revised prior to construction. The original (JMM, 1991) model SV, SE, and SQ data for the Upper Las Vegas Wash detention basin were replaced using the SV, SE, and SQ data from HEC-1 models prepared by B&V (1993). The B&V stage-storage and stage-discharge relationships for the Upper Las Vegas Wash detention basin were reviewed and found to adequately reflect as-built conditions.

- The stage-discharge relationship for the North Las Vegas Wash detention basin was updated to reflect the existing three-pipe outlet structure with a four-feet high, 53-feet wide upstream barrier wall. The 1991 JMM model had assumed a four-pipe outlet structure based on preliminary design data; however, two of the structure's original five outlet pipes were subsequently blocked following construction of the Upper Las Vegas Wash detention basin. The original (JMM, 1991) model SQ data for the North Las Vegas Wash detention basin, for stages above seven feet, were replaced using the discharge data presented by B&V (1993) for a three-pipe outlet structure. Discharges below about seven feet stage were found to be controlled by the upstream barrier wall which was not represented in any of the previously

outlet rating curves. The rating curve for the barrier wall was computed for the current study by assuming orifice flow through the weep holes, plus weir flow at stages above four feet.

A Spring Mountain 500-year storm HEC-1 model was developed for the present study by modifying the 100-year model to include 500-year rather than 100-year rainfall amounts. This differs from the approach taken in the previous JMM (1991) FIS study in which 500-year flows were estimated by extrapolation of the flows simulated for 10-, 50-, and 100-year return periods. The previous method is likely to underestimate 500-year flows in the Upper Las Vegas Wash system because the detention basins are sized to be filled during a 100-year event. A substantial loss of flow control should therefore be expected at more extreme events due to spillway flow.

Spring Mountain storm 500-year rainfall amounts for each model subbasin were determined by extrapolation of the rainfall amounts from the JMM (1991) 10-, 50-, and 100-year Spring Mountain storm HEC-1 models.

Interbasin Storm Files

Interbasin storm 10- through 500-year rainfall HEC-1 files for the present study are based on the 100-year Interbasin storm HEC-1 file prepared by B&V (1993). This storm covers the Las Vegas Wash basin area beginning immediately downstream from the Upper Las Vegas Wash detention basin and extending to the outlet of the North Las Vegas detention basin. Hydraulic characteristics for the North Las Vegas detention basin were revised to be the same as for the updated Spring Mountain storm models discussed above.

Subbasin rainfall amounts for the 100-year Interbasin storm are as presented in the original B&V model. Rainfall amounts for 10- and 50- year storms are based on the 10- and 50-year subbasin rainfall amounts presented by JMM (1991) for the Lower Central Valley storm, which covers all but two of the subbasins included in the Interbasin storm. Rainfall amounts from the JMM (1991) 10- and 50-year models were divided by a factor of 0.62 to remove the depth-area correction factor which had been applied to subbasin rainfall amounts in the original development of the Lower Central Valley models. 10- and 50- year, 6-hour rainfall amounts for the two subbasins (104 and 105) not covered by the Lower Central Valley models were determined from NOAA Atlas 2 for Nevada. The 10- and 50-year atlas amounts were increased by factors of 1.24 and 1.39 respectively, as recommended by the CCRFCD (1990). A depth-area correction factor of 0.66 was applied for all Interbasin storms.

Subbasin rainfall amounts for the 500-year Interbasin storm were determined by extrapolation of rainfall amounts from the 10-, 50-, and 100-year Interbasin storm models.

Input files for all HEC-1 models modified or created for the purposes of this study are provided in digital form on a diskette which accompanies this report.

1.4 Revised FIS Discharges

Table 1 summarizes the results of the HEC-1 modeling at various points along the Upper Las Vegas Wash system. Computation nodes are shown in Figure 1-3. Table 2 compares the current model results with the previously adopted FIS flows.

The current model results for 10- through 100-year return periods are slightly lower than the previously-adopted FIS discharges. We do not consider the differences to be sufficiently large to warrant changing the previously-published 10- through 100-year flows which are currently being used by others for concurrent (downstream) floodplain mapping analyses.

The revised hydrologic analysis indicates a 500-year discharge downstream from the North Las Vegas detention basin which is about 80% larger than previously assumed. This increase in the 500-year discharge is due to a loss of detention basin flow control that was not specifically addressed in the previous FIS analysis.

	Interbasin		**2,939**	**6,751**	**8,537**	13,077
Diversion Dike Overflow at NLVDB	Spring Mtn	DIVDIKE	0	0	0	**6,838**
	Interbasin		0	0	**194**	3,226
NLVDB Pipe and Spillway Outflow (Max stage, feet above 2108 feet)	Spring Mtn	NLVDET	1,292 (9.90)	2,186 (22.5)	2,839 (27.42)	6,322 (31.44)
Total Discharge below NLVDB	Spring Mtn	2 combined	**1,292**	**2,186**	**2,839**	**8,988**
	Interbasin		1,220	2,074	2,345	5,438
Diversion along Railway	Spring Mtn	RRCHANNL	0	0	0	2,236
ULVW at Railway Bridge	Spring Mtn	RRBRIDGE	1,281	2,183	2,833	6,083
Diversion at King Charles Channel	Spring Mtn	KCHAR	1,024	1,746	2,266	4,866
ULVW at Hwy 15	Spring Mtn	I15 below KCHAR	256	437	567	1,217

Definitions:

ULVWDB = Upper Las Vegas Wash Detention Basin
NLVDB = North Las Vegas Detention Basin
ULVW = North Las Vegas Wash

Assumptions for Railway and King Charles Diversions:

HEC-1 model output for diversions from the main ULVW into the Railway and King Charles Channels are based on the following approximate relationships:

ULVW Flow cfs	Diversion to Railway Channel	NLVW Flow cfs	Diversion to King Charles
0	0	0	0
6,000	0	1,000	800
20,000	13,500	10,000	8,000

Storms:

Spring Mountain: a 136 square mile storm over the Spring Mountains upstream from the ULVWDB.
Interbasin: a 54 square mile storm between the ULVWDB and NLVDB

West Range Wash Diversion flows to NLVDB

West Range Wash Diversion flows were not modeled as part of the present study. Three estimates of the 100-year peak inflow from this 48.2 square mile basin are readily available as follows:

From HEC-1 model by Boyle (1991): 6,584 cfs
From COE Regional Curve: 48.2 times 155 cfs/sq mi: 7,471 cfs
Adjust Interbasin storm flows above DIVDIKE for basin area, 8,537 times (48/54):7,588 cfs

HEC-1 files listed below were prepared by Northwest Hydraulic Consultants Inc (NHC) for analysis of the North Las Vegas Wash and have not yet been approved. by FEMA. All files were based on files previously prepared by James M Montgomery (JMM) for the Clark County Regional Flood Control District (CCRFCD) Las Vegas Valley Flood Insurance Study Hydrology Report, dated September 1991. Source files for the Spring Mountain, Interbasin, and Lower Central Valley Storms were obtained in digital form from the CCRFCD and were all dated January 1991. The model for the Range Wash Storm was copied from the Boyle Engineering Corporation Technical Support Data Notebook for Clark County, Nevada and Incorporated areas, Range Wash Flood Insurance Restudy, Volume 2 Part 1.

Three modifications were made to the JMM HEC-1 files.

1. The files were updated to reflect the as-built stage-storage-outflow characteristics for the Upper Las Vegas Wash Detention Basin, which had not been constructed at the time of the JMM studies. The relationships used in the revised models correspond to data from HEC-1 models prepared in August 1993 by Black & Veatch for the report titled "North Las Vegas Detention Basin Outlet Modification Report."

2. The stage-outflow relationship for the North Las Vegas Detention was revised to reflect the three-pipe outflow configuration which presently exists (two pipes were blocked following completion of the Upper Las Vegas Wash Detention Basin). Also, the stage-outflow relation at low water levels was corrected to reflect the hydraulic control presented by a four-foot high wall (with 13 1-foot square weep holes) which is located immediatly upstream from the pipe inlets. This control appear to have been overlooked in the previous analyses.

3. 500-year storm HEC-1 models were created from the 100-year models by replacing all rainfall (PB Cards) data with 500-year amounts. 500-year rainfall amounts were determined for each subbasin by frequency extrapolation of rainfall amounts found in the JMM 10-. 50-, and 100-year models for each storm centering.

Modifications to the East and West Range Washes 100-Year, 6-Hour Storm, Future Conditions with Alternative IV Facilities, dated 6/5/92, included inserting the stage-outflow relationship for the North Las Vegas Detention described above in item 2. In addition the 100-Year rainfall (PB Cards) data were replaced with extrapolated 500-year amounts as described in item 3.

The HEC-1 models summarized below were used in the draft 1996 NHC Flood Insurance Study review submittal to FEMA.

SP_010.H1I - 10-year Spring Mountain Storm, modified from JMM

HEC-1 file SPR10.DAT as described above.

SP_050.H1I - 50-year Spring Mountain Storm, modified from JMM HEC-1 file SPR50.DAT as described above.

SP_100.H1I - 100-year Spring Mountain Storm, modified from JMM HEC-1 file SPR100.DAT as described above.

SP_500.H1I - 500-year Spring Mountain Storm, modified from JMM HEC-1 file SPR100.DAT as described above.

LC_010.H1I - 10-year Lower Central Valley Storm, modified from JMM HEC-1 file ULVW10.DAT as described above.

LC_050.H1I - 50-year Lower Central Valley Storm, modified from JMM HEC-1 file ULVW50.DAT as described above.

LC_100.H1I - 100-year Lower Central Valley Storm, modified from JMM HEC-1 file ULVW100.DAT as described above.

LC_500.H1I - 500-year Lower Central Valley Storm, modified from JMM HEC-1 file ULVW100.DAT as described above.

RW_500.H1I - 500-year Range Wash Storm, modified from Boyle HEC-1 file described in items 2 and 3.

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
SPRING MOUNTAIN 10-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Two modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
NORTHERN LAS VEGAS WASH - WESTERN TRIBUTARY
SPRING MOUNTAIN 10-YEAR STORM EXISTING CONDITIONS

Based on Northern Las Vegas Wash HEC-1 model by Black & Veatch, 8/89
CCRFCD DARF = 0.56 for 136 sq mi storm (JR card = 0.903) - JMM, 1/91
The storm area of 136 sq mi reflects the Spring Mtn Storm minus the portion within the Gowan Area (which is not tributary to the Upper Las Vegas Wash Detention Basin diversion)
Convert nat. channels fr/kinematic wave to Muskingum Routing-JMM, 7/90
All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

This run models the diversion from the West Tributary to the proposed

Upper Las Vegas Wash Detention Basin, 1/91

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
SPRING MOUNTAIN 50-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Two modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
NORTHERN LAS VEGAS WASH - WESTERN TRIBUTARY
SPRING MOUNTAIN 50-YEAR STORM EXISTING CONDITIONS

Based on Northern Las Vegas Wash HEC-1 model by Black & Veatch, 8/89
CCRFCD DARF = 0.56 for 136 sq mi storm (JR card = 0.903) - JMM, 1/91
The storm area of 136 sq mi reflects the Spring Mtn Storm minus the portion within the Gowan Area (which is not tributary to the Upper Las Vegas Wash Detention Basin diversion)
Convert nat. channels fr/kinematic wave to Muskingum Routing-JMM, 7/90
All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

This run models the diversion from the West Tributary to the proposed

Upper Las Vegas Wash Detention Basin, 1/91

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
SPRING MOUNTAIN 100-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Two modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
NORTHERN LAS VEGAS WASH - WESTERN TRIBUTARY
SPRING MOUNTAIN 100-YEAR STORM EXISTING CONDITIONS

Based on Northern Las Vegas Wash HEC-1 model by Black & Veatch, 8/89
CCRFCD DARF = 0.56 for 136 sq mi storm (JR card = 0.903) - JMM, 1/91
The storm area of 136 sq mi reflects the Spring Mtn Storm minus the portion within the Gowan Area (which is not tributary to the Upper Las Vegas Wash Detention Basin diversion)
Convert nat. channels fr/kinematic wave to Muskingum Routing-JMM, 7/90
All routing steps immediately d/s of a diversion converted to Muskingum rouing to avoid zero flow, 8/90

This run models the diversion from the West Tributary to the proposed

Upper Las Vegas Wash Detention Basin, 1/91

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSXX- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

                    *DIAGRAM
              1     ID        FEMA FLOOD INSURANCE STUDY, 1996
              2     ID        UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
              3     ID        SPRING MOUNTAIN 500-YEAR STORM
              4     ID
              5     ID        Current (05/96) model based on a HEC-1 model prepared by James M
              6     ID        Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance
              7     ID        Study Hydrology Report dated 9/91.  Three modifications were made
              8     ID        to the source model.  First, Upper Las Vegas Detention Basin storage
              9     ID        and outflow characteristics were revised to reflect the as-built
             10     ID        configuration described by construction drawings dated 5/91 and HEC-1
             11     ID        models prepared in 1993 by Black & Veatch.  Second, the stage-outflow
             12     ID        relationship for the North Las Vegas Detention Basin was revised
             13     ID        to reflect the current three-pipe outlet condition (two of the five
             14     ID        pipes were blocked following construction of the upper basin) and the
             15     ID        hydraulic control created by the 4-foot high barrier wall located
             16     ID        upstream from the pipe inlets.  Third, the source 100-year model
             17     ID        was converted to reflect 500-year conditions by replacing all PB
             18     ID        cards with 500-year amounts.  500-year rainfall amounts were
             19     ID        determined for each subbasin by frequency extrapolation of the
             20     ID        amounts presented by JMM in the 10-, 50-, and 100-year Spring
             21     ID        Mountain Storm models.
             22     ID
             23     ID
             24     ID        Remaining comments are from the original model dated 1/91.

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
SPRING MOUNTAIN 500-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) *in 1/91 for the Las Vegas* Valley Flood Insurance Study Hydrology Report dated 9/91. Three modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and *outflow characteristics* were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow *relationship* for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets. Third, the source 100-year model was converted to reflect 500-year conditions by replacing all PB cards with 500-year amounts. 500-year rainfall amounts were determined for each subbasin by frequency *extrapolation of the* amounts presented by JMM in the 10-, 50-, and 100-year Spring Mountain Storm models.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
NORTHERN LAS VEGAS WASH - WESTERN TRIBUTARY

SPRING MOUNTAIN 500-YEAR STORM (100-year model with 500-year rain)

Based on Northern Las Vegas Wash HEC-1 model by Black & Veatch, 8/89
CCRFCD DARF = 0.56 for 136 sq mi storm (JR card = 0.903) - JMM, 1/91
The storm area of 136 sq mi reflects the Spring Mtn Storm minus the portion within the Gowan Area (which is not tributary to the Upper Las Vegas Wash Detention Basin diversion)
Convert nat. channels fr/kinematic wave to Muskingum Routing-JMM, 7/90
All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

This run models the diversion from the West Tributary to the proposed Upper Las Vegas Wash Detention Basin, 1/91

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THR DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
LOWER CENTRAL VALLEY 10-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Two modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
Northern Las Vegas Wash - FIS FLOWS
Prepared by James M. Montgomery, Consulting Engineers, Inc., 1/91

Based on Black & Veatch Northern Las Vegas Wash HEC-1 Model, 8/89
Lower Central Valley 10-Year Storm, Existing Conditions
Additional subareas and facilities from Wallace, 7/88 (EAP.H1) & 8/88 (EPT.H1); VTN, 1/90 (3900EX4.DAT); & B&V La Madre Area, (LAME.DAT)
PB & CN values adjusted by JMM to be consistent with B&V values, 8/90

All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

Gowan-North & Gowan-South Detention Basins & Outfall Channel, Buffalo Channel, Cheyenne Channel, Angel Park Detention Basin & Outfall Channel and Hualapai Diversion included, 8/90

This data file models DARF's at certain locations where FIS flows are required. The original B&V data file used a factor of 0.62; ratios of this factor are used in the JR card to model DA's at the points of interest (JMM DARF's extracted from CCRFCD Design Manual):

PT OF INTEREST	AREA (SQ MI)	DARF	DARF/0.62	RATIO
RRBRIDGE, NC5, & 304	60.7 - 64.5	0.66	1.06	1
ACHANNL	111.6	0.59	0.95	2
NCHANNL	172.2	0.53	0.85	3

THIS PROGRAM REPLACES ALL *PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB,* AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
LOWER CENTRAL VALLEY 50-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Two modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
Northern Las Vegas Wash - FIS FLOWS
Prepared by James M. Montgomery, Consulting Engineers, Inc., 1/91

Based on Black & Veatch Northern Las Vegas Wash HEC-1 Model, 8/89
Lower Central Valley 50-Year Storm, Existing Conditions
Additional subareas and facilities from Wallace, 7/88 (RAP.H1) & 8/88 (EPT.H1); VTN, 1/90 (3900EX4.DAT); & B&V La Madre Area, (LAME.DAT)
PB & CN values adjusted by JMM to be consistent with B&V values, 8/90

All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

Gowan-North & Gowan-South Detention Basins & Outfall Channel, Buffalo Channel, Cheyenne Channel, Angel Park Detention Basin & Outfall Channel and Hualapai Diversion included, 8/90

This data file models DARF's at certain locations where FIS flows are required. The original B&V data file used a factor of 0.62; ratios of this factor are used in the JR card to model DA's at the points of interest (JMM DARF's extracted from CCRFCD Design Manual):

PT OF INTEREST	AREA (SQ MI)	DARF	DARF/0.62	RATIO
RRBRIDGE, NC5, & 304	60.7 - 64.5	0.66	1.06	1
ACHANNL	111.6	0.59	0.95	2
NCHANNL	172.2	0.53	0.85	3

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

              4     ID
              5     ID          Current (05/96) model based on a HEC-1 model prepared by James M
              6     ID          Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance
              7     ID          Study Hydrology Report dated 9/91.  Two modifications were made
              8     ID          to the source model.  First, Upper Las Vegas Detention Basin storage
              9     ID          and outflow characteristics were revised to reflect the as-built
             10     ID          configuration described by construction drawings dated 5/91 and HEC-1
             11     ID          models prepared in 1993 by Black & Veatch.  Second, the stage-outflow
             12     ID          relationship for the North Las Vegas Detention Basin was revised
             13     ID          to reflect the current three-pipe outlet condition (two of the five
             14     ID          pipes were blocked following construction of the upper basin) and the
             15     ID          hydraulic control created by the 4-foot high barrier wall located
             16     ID          upstream from the pipe inlets.
             17     ID
             18     ID          Remaining comments are from the original model dated 1/91.

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
LOWER CENTRAL VALLEY 100-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Two modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
Northern Las Vegas Wash - FIS FLOWS
Prepared by James M. Montgomery, Consulting Engineers, Inc., 1/91

Based on Black & Veatch Northern Las Vegas Wash HEC-1 Model, 8/89
Lower Central Valley 100-Year Storm, Existing Conditions
Additional subareas and facilities from Wallace, 7/88 (EAP.H1) & 8/88 (EPT.H1); VTN, 1/90 (3900EX4.DAT); & B&V La Madre Area, (LAMB.DAT)
PB & CN values adjusted by JMM to be consistent with B&V values, 8/90

All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

Gowan-North & Gowan-South Detention Basins & Outfall Channel, Buffalo Channel, Cheyenne Channel, Angel Park Detention Basin & Outfall Channel and Hualapai Diversion included, 8/90

This data file models DARF's at certain locations where FIS flows are required. The original B&V data file used a factor of 0.62; ratios of this factor are used in the JR card to model DA's at the points of interest (JMM DARF's extracted from CCRFCD Design Manual):

PT OF INTEREST	AREA (SQ MI)	DARF	DARF/0.62	RATIO
RRBRIDGE, NCS, & 304	60.7 - 64.5	0.66	1.06	1
ACHANNL	111.6	0.59	0.95	2
NCHANNL	172.2	0.53	0.85	3

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

                *DIAGRAM
             1  ID          FEMA FLOOD INSURANCE STUDY, 1996
             2  ID          UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
             3  ID          LOWER CENTRAL VALLEY 500-YEAR STORM
             4  ID
             5  ID          Current (05/96) model based on a HEC-1 model prepared by James M
             6  ID          Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance
             7  ID          Study Hydrology Report dated 9/91.  Three modifications were made
             8  ID          to the source model.  First, Upper Las Vegas Detention Basin storage
             9  ID          and outflow characteristics were revised to reflect the as-built
            10  ID          configuration described by construction drawings dated 5/91 and HEC-1
            11  ID          models prepared in 1993 by Black & Veatch.  Second, the stage-outflow
            12  ID          relationship for the North Las Vegas Detention Basin was revised
            13  ID          to reflect the current three-pipe outlet condition (two of the five
            14  ID          pipes were blocked following construction of the upper basin) and the
            15  ID          hydraulic control created by the 4-foot high barrier wall located
            16  ID          upstream from the pipe inlets.  Third, the source 100-year model
            17  ID          was converted to reflect 500-year conditions by replacing all PB
            18  ID          cards with 500-year amounts.  500-year rainfall amounts were
            19  ID          determined for each subbasin by frequency extrapolation of the
            20  ID          amounts presented by JMM in the 10-, 50-, and 100-year Lower Central
            21  ID          Valley Storm models.
            22  ID
            23  ID          Remaining comments are from the original model dated 1/91.

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
LOWER CENTRAL VALLEY 500-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by James M Montgomery (JMM) in 1/91 for the Las Vegas Valley Flood Insurance Study Hydrology Report dated 9/91. Three modifications were made to the source model. First, Upper Las Vegas Detention Basin storage and outflow characteristics were revised to reflect the as-built configuration described by construction drawings dated 5/91 and HEC-1 models prepared in 1993 by Black & Veatch. Second, the stage-outflow relationship for the North Las Vegas Detention Basin was revised to reflect the current three-pipe outlet condition (two of the five pipes were blocked following construction of the upper basin) and the hydraulic control created by the 4-foot high barrier wall located upstream from the pipe inlets. Third, the source *100-year model* was converted to reflect 500-year conditions by replacing all PB cards with 500-year amounts. 500-year rainfall amounts were determined for each subbasin by frequency extrapolation of the amounts presented by *JMM in the 10-, 50-, and 100-year* Lower Central Valley Storm models.

Remaining comments are from the original model dated 1/91.

CCRFCD LAS VEGAS VALLEY MASTER PLAN UPDATE
Northern Las Vegas Wash - FIS FLOWS
Prepared by James M. Montgomery, Consulting Engineers, Inc., 1/91

Based on Black & Veatch Northern Las Vegas Wash HEC-1 Model, 8/89
Lower Central Valley 100-Year Storm, Existing Conditions
Additional subareas and facilities from Wallace, 7/88 (EAP.H1) & 8/88 (EPT.H1); VTN, 1/90 (3900RX4.DAT); & B&V La Madre Area, (LAME.DAT)
PB & CN values adjusted by JMM to be consistent with B&V values, *8/90*

All routing steps immediately d/s of a diversion converted to Muskingum routing to avoid zero flow, 8/90

Gowan-North & Gowan-South Detention Basins & Outfall Channel, Buffalo Channel, Cheyenne Channel, Angel Park Detention Basin & Outfall Channel and Hualapai Diversion included, 8/90

This data file models DARF's at certain locations where FIS flows are

required. The original B&V data file used a factor of 0.62; ratios of this factor are used in the JR card to model DA's at the points of interest (JMM DARF's extracted from CCRFCD Design Manual):

PT OF INTEREST	AREA (SQ MI)	DARF	DARF/0.62	RATIO
RRBRIDGE, NC5, & 304	60.7 - 64.5	0.66	1.06	1
ACHANNL	111.6	0.59	0.95	2
NCHANNL	172.2	0.53	0.85	3

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
INTERBASIN 10-year STORM

Current (05/96) model based on a HEC-1 model prepared by Black&Veatch in 8/93 for the design of outlet modifications at the North Las Vegas Detention Basin (NLVDB). This storm centering generates the highest 100-year inflows to the NLVDB.

Modifications to the original B&V model were to adjust the outlet

rating for the NLVDB to reflect the four-foot high barrier wall in front of the 3-pipe outlet. Additional models were created to represent 10, 50, and 500-year storms.

Remaining comments are from the original model dated 8/93.

This storm also known as "Gayles Storm" simulates a 54 square mile storm centered downstream of the Upper Las Vegas Wash Detention Basin but upstream of the North Las Vegas Detention Basin. This model is based original model developed by Black & Veatch during the predesign study for Upper Las Vegas Wash Detention Basin.

Storm Area: 54.37 sq. miles
DARF: 0.66 (CCRFCD Drainage Manual)

10-yr Precipitation Adjustment Ratio: 1.24 (CCRFCD Drainage Manual)
50-yr Precipitation Adjustment Ratio: 1.39 (CCRFCD Drainage Manual)
100-yr Precipitation Adjustment Ratio: 1.43 (CCRFCD Drainage Manual)

JR Card includes DARF for model
PB Cards are adjusted rainfall depth, NOAA Atas II amounts
times adjustment ratios given above.
PB Cards for 500-year storm based on frequency extrapolation of
10, 50, and 100-year data after precipitation ratio adjustments.

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
INTERBASIN 50-year STORM

Current (05/96) model based on a HEC-1 model prepared by Black&Veatch in 8/93 for the design of outlet modifications at the North Las Vegas Detention Basin (NLVDB). This storm centering generates the highest 100-year inflows to the NLVDB.

Modifications to the original B&V model were to adjust the outlet

rating for the NLVDB to reflect the four-foot high barrier wall in front of the 3-pipe outlet. Additional models were created to represent 10, 50, and 500-year storms.

Remaining comments are from the original model dated 8/93.

This storm also known as "Gayles Storm" simulates a 54 square mile storm centered downstream of the Upper *Las Vegas Wash Detention Basin* but upstream of the North Las Vegas Detention Basin. This model is based original model developed by Black & Veatch during the predesign study for Upper Las Vegas Wash Detention Basin.

Storm Area: 54.37 sq. miles
DARF: 0.66 (CCRFCD Drainage Manual)

10-yr Precipitation Adjustment Ratio: 1.24 (CCRFCD Drainage Manual)
50-yr Precipitation Adjustment Ratio: 1.39 (CCRFCD Drainage Manual)
100-yr Precipitation Adjustment Ratio: 1.43 (CCRFCD Drainage Manual)

JR Card includes DARF for model
PB Cards are adjusted rainfall depth, NOAA Atas II amounts times adjustment ratios given above.
PB Cards for 500-year storm based on frequency extrapolation of 10, 50, and 100-year data after precipitation ratio adjustments.

THIS PROGRAM *REPLACES* ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
INTERBASIN 100-YEAR STORM

Current (05/96) model based on a HEC-1 model prepared by Black&Veatch in 8/93 for the design of outlet modifications at the North Las Vegas Detention Basin (NLVDB). This storm centering generates the highest 100-year inflows to the NLVDB.

Modifications to the original B&V model were to adjust the outlet

```
                    rating for the NLVDB to reflect the four-foot high barrier wall in
                    front of the 3-pipe outlet.  Additional models were created to
                    represent 10, 50, and 500-year storms.

                    Remaining comments are from the original model dated 8/93.

                  This storm also known as "Gayles Storm" simulates a 54 square mile
                  storm centered downstream of the Upper Las Vegas Wash Detention Basin
                  but upstream of the North Las Vegas Detention Basin.  This model is based
                  original model developed by Black & Veatch during the predesign study for
                  Upper Las Vegas Wash Detention Basin.

                            Storm Area:     54.37 sq. miles
                            DARF:           0.66 (CCRFCD Drainage Manual)

                     10-yr  Precipitation Adjustment Ratio: 1.24 (CCRFCD Drainage Manual)
                     50-yr  Precipitation Adjustment Ratio: 1.39 (CCRFCD Drainage Manual)
                    100-yr  Precipitation Adjustment Ratio: 1.43 (CCRFCD Drainage Manual)

                  JR Card includes DARF for model
                  PB Cards are adjusted rainfall depth, NOAA Atas II amounts
                     times adjustment ratios given above.
                  PB Cards for 500-year storm based on frequency extrapolation of
                     10, 50, and 100-year data after precipitation ratio adjustments.

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

FEMA FLOOD INSURANCE STUDY, 1996
UPPER LAS VEGAS WASH, CLARK COUNTY, NEVADA
INTERBASIN 500-year STORM

Current (05/96) model based on a HEC-1 model prepared by Black&Veatch in 8/93 for the design of outlet modifications at the North Las Vegas Detention Basin (NLVDB). This storm centering generates the highest 100-year inflows to the NLVDB.

Modifications to the original B&V model were to adjust the outlet

rating for the NLVDB to reflect the four-foot high barrier wall in front of the 3-pipe outlet. Additional models were created to represent 10, 50, and 500-year storms.

Remaining comments are from the original model dated 8/93.

This storm also known as "Gayles Storm" simulates a 54 square mile storm centered downstream of the Upper Las Vegas Wash Detention Basin but upstream of the North Las Vegas Detention Basin. This model is based original model developed by Black & Veatch during the predesign study for Upper Las Vegas Wash Detention Basin.

Storm Area: 54.37 sq. miles
DARF: 0.66 (CCRFCD Drainage Manual)

10-yr Precipitation Adjustment Ratio: 1.24 (CCRFCD Drainage Manual)
50-yr Precipitation Adjustment Ratio: 1.39 (CCRFCD Drainage Manual)
100-yr Precipitation Adjustment Ratio: 1.43 (CCRFCD Drainage Manual)

JR Card includes DARF for model
PB Cards are adjusted rainfall depth, NOAA Atas II amounts times adjustment ratios given above.
PB Cards for 500-year storm based on frequency extrapolation of 10, 50, and 100-year data after precipitation ratio adjustments.

THIS PROGRAM REPLACES ALL PREVIOUS VERSIONS OF HEC-1 KNOWN AS HEC1 (JAN 73), HEC1GS, HEC1DB, AND HEC1KW.

THE DEFINITIONS OF VARIABLES -RTIMP- AND -RTIOR- HAVE CHANGED FROM THOSE USED WITH THE 1973-STYLE INPUT STRUCTURE.
THE DEFINITION OF -AMSKK- ON RM-CARD WAS CHANGED WITH REVISIONS DATED 28 SEP 81. THIS IS THE FORTRAN77 VERSION
NEW OPTIONS: DAMBREAK OUTFLOW SUBMERGENCE , SINGLE EVENT DAMAGE CALCULATION, DSS:WRITE STAGE FREQUENCY,
DSS:READ TIME SERIES AT DESIRED CALCULATION INTERVAL LOSS RATE:GREEN AND AMPT INFILTRATION
KINEMATIC WAVE: NEW FINITE DIFFERENCE ALGORITHM

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

The Upper Las Vegas Wash Flood Insurance Study area extends from the upstream end of the Upper Las Vegas Wash Diversion Berm/Channel downstream through a series of flood control structures to the terminus of the King Charles channel at its confluence with the A Channel. The wash was separated into 3 subreaches:

- Subreach 1 - Upper Las Vegas Wash Interception Berm/Channel to Upper Las Vegas Detention Basin (ULVDB)
- Subreach 2 - ULVDB to the North Las Vegas Detention Basin (NLVDB)
- Subreach 3 - NLVDB to the terminus of the King Charles channel (KCC) at its confluence with the A Channel near I-15
- Subreach 4 - N Channel from the diversion at King Charles to the Interstate 10 and N Channel culvert

The water surface profiles for each subreach were modeled using HEC-2. The discharges for the models were computed using HEC-1. Listed below are the HEC-2 models used by subreach.

Subreach 1

ulvdv5	ULVDB to upstream end of the Upper Las Vegas Diversion Berm (upstream study limits) subcritical model, 10-500 yr profiles

Subreach 2

nlvdbv6b	NLVDB to Upper Las Vegas Detention Basin (ULVDB) subcritical model, 10-500 yr profiles

Subreach 3

lnlvwo16	Downstream study limit at A Channel to North Las Vegas Detention Basin (NLVDB) subcritical model, 10-50 yr profiles
ln-50026	Craig Road Bridge to NLVDB subcritical model, 100 -500 yr profiles
kgsbwo2	King Charles Channel, A Channel to Craig Road Bridge, subcritical model, 100-500 yr profiles
kgscwo2	King Charles Channel , A Channel to Craig Road Bridge, supercritical model, 10-500 yr profiles

The "N" Channel Diversion diverts flow from the King Charles Channel into a lined concrete channel between the King Charles Channel and I-15. This channel was modeled as a separate subreach.

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

Subreach 4

nch-spwo N Channel supercritical model, 10-50 yr profiles

nch-spwob N Channel supercritical model, 100 - 500 yr profile

Subreach 1 - ULV Interception Berm/Channel (sta 749+97) to the ULVDB (590+59)

A subcritical/critical water surface profile was modeled from downstream to upstream from the Upper Las Vegas Detention Basin to the upstream end of the Upper Las Vegas Interception Berm (file name: ULVDV5.dat). The peak discharge for each return period was used throughout the model subreach to compute the water surface profile.

Discharges: Q_{10}=3465 cfs, Q_{50}=10312, Q_{100}=14737 cfs, Q_{500}=24938 cfs
Wash Manning's n = 0.04
Concrete, Soil Cement n = 0.025
expansion coeff=0.3
contraction coeff =0.1

The Project Officer advised us to use the upslope (northerly) floodplain boundary as the limit of study between the ULV Diversion Berm/Channel to the ULVDB. Therefore, the flood hazards on the fan surface and inflowing arroyos were not determined or mapped.

Listed below by station are comments regarding the characteristics of the wash.

Sta	Description
749+97	Upstream extent of HEC-2 model, at the upstream end of the Upper Las Vegas Wash Interceptor Berm/Channel. The interceptor berm extends from station 660+60 to 749+97 the right bank is lined with rock (d50=12"), the channel bottom is compacted native material. The left bank is lined with roller compacted concrete. A Manning's n of 0.04 was used throughout the subreach.
668+14	Upstream end of 4.5' high rock grade control structure
666+60	Downstream end of rock grade control apron
660+60	Downstream end of Interceptor berm where the interceptor channel transitions into the wash. Manning's "n" for wash reach to basin=0.04
590+59	Downstream end of the HEC-2 model. The ULVDB Pool elevations were used in the model as the starting water surface elevations.

Return period (yr)	10	50	100	500
Discharge (cfs)	3465	10312	14737	24938
ULVDB Pool Elev (ft)	2351.3	2367.0	2372.4	2375.7

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

Subreach 2 - ULVDB (sta 564+87) to NLVDB (306+80)

A subcritical/critical water surface profile was modeled from downstream to upstream from the NLVDB to the ULVDB (file name: NLVDB6B.dat). The peak discharges in the wash for the 10 - 100 year events are produced by the Interbasin Storm. The peak discharge in the wash for the 500 year event is produced by the Spring Mountain Storm. A station equation was placed at Station 311+00 ahead and 299+01.96 back to maintain the stationing established in the With Diversion Dike condition. This equation is only applicable to the Without Diversion Dike condition. The 10 yr and 50 yr FIS profiles are not shown between stations 267+00 and 311+00, since they follow a different hydraulic baseline alignment.

Wash Discharges: Q_{10}=2939 cfs (IB), Q_{50}=6751 (IB), Q_{100}=8537 cfs, Q_{500}=19217 cfs
Wash Manning's n = 0.04
expansion coeff=0.3
contraction coeff =0.1

The Project Officer advised us to use the upslope (northerly) floodplain boundary as the limit of study between the ULVDB to the NLVDB.

Listed below by station are comments regarding the characteristics of the wash.

Sta	Description
564+87	Upstream extent of model; The source of the cross sections downstream of Upper Las Vegas Detention Basin Spillway are from Upper Las Vegas Detention Basin Plans. The peak discharges for the Interbasin storm and Spring Mountain Storm were used in the HEC-2 modeled from 564+87 to 309+35 (Q_{10}=2939 cfs (IB), Q_{50}=6751 (IB), Q_{100}=8537 cfs, Q_{500}=19217 cfs)
564+97 -558+70	Transition from spillway to wash; cross-sections cut from Upper Las Vegas Detention Basin Plans. The lining is native material over a roller compacted concrete toe. The spillway apron toe is 26ft below the invert elevation of the transition
555+70 -320+44	The wash sections were obtained by aerial photogrammetry
315+00 -312+35	Wash sections were obtained from the 1996 Kenney Aerial Topographic Maps

The NLVDB Diversion Dike diverts flow from the historical wash channel into the North Las Vegas Detention Basin. The was changes invert slope (0.01 in the wash to 0.002 in the diversion channel) and bottom width (120 feet in the wash to 70 feet in the diversion channel). Diversion channel sections were obtained from the project plans.

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

An 'n' of 0.025 was used in the lined channel.

The HEC-2 model NLDVB6B extends into the North Las Vegas Detention Basin. This alignment is different from the hydraulic baseline alignment, which contains a station equation at the diversion dike, and continues down the historical wash channel through the diversion dike. NLDVB6B was used to general computed 10 through 100 year water surfaces in the diversion channel and upstream in the wash. The results of this model indicated that the 100-year discharge would slightly overtop the diversion dike crest of 2142.0 feet. The computed water surface elevations in the model do not take into account uncertainties introduced by the potential effects of sediment deposition at the change in direction of flow at the dike, changes from super- to subcritical flow, superelevation at the bend, or waves, all of which could increase the actual water surface elevations. Based on this analysis, the performance of the dike to withstand the 100-year event was questioned (See *Review of Flood Control Structures, Volume 2*), and the dike was assumed (for this study case) not to remain in place at discharges equal to or greater than the 100-year peak discharge.

Computed water surface elevations in the NLVDB6B model for the 10- and 50-year discharges are at least three feet below the top of the dike and are therefore diverted into the basin. Removal of the dike in the 100- and 500-year discharges, and modeling these flows down the historical wash channel without the dike in place, would produce lower water surfaces than the NLVDB6B model at the dike and immediately upstream. However, because the dike would likely remain in place until overtopped, the NLVDB6B model was used to set 100- and 500-year water surface elevations in the vicinity of the dike, downstream of the dike in the diversion channel, and immediately upstream of the dike in the wash. The 100- and 500-year water surfaces are coincident at the dike and immediately upstream due to the assumption that the dike remains in place up to the 100-year discharge, and then is removed.

307+65 This section represents the upstream end of the control structure transition which serves to constrict the flow, causing wash flows over approximately 8350 cfs to begin diverting flow over the dike. The flow splits between the flow into the basin and over the dike were calculated in the HEC-1 models using a rating table developed in HEC-2, refer to the DIVDIKE node in the HEC-1 models.

306+80 The downstream end of control structure transition. The channel slope changes from 0.2% upstream in the diversion channel to 0.76% downstream in the basin inlet channel.

306+50 The downstream end of control structure is lined with soil cement. Critical depth was computed in both sub and super critical runs at this section. A stable supercritical water surface profile was computed downstream of this section to the downstream end of the inlet channel. The supercritical flow regime is drowned out by the basin stage at the time of the peak

discharge. Upstream of this section in the diversion channel, approximately 200 cfs is diverted during the 100 year event and 6838 cfs during the 500 year event over the dike. The resulting flows downstream of this section are 8343 and 10989 cfs for the 100 and 500 year events, respectively.

300+67 Supercritical flow 10-500 yr, BFE's set by maximum basin stage computed in HEC-1.

294+85 Supercritical flow 10-500 yr, BFE's set by maximum basin stage computed in HEC-1.

The maximum basin stages in the NLVDB for the 10 - 100-yr were determined using the respective Spring Mountain HEC-1 models for each recurrence interval. This storm produces higher runoff volumes than the Interbasin Storm, and is thus the critical storm for determining basin-pool elevations. The Spring Mountain discharges attenuated by the ULVDB are conveyed through the NLVDB diversion dike channel with adequate freeboard for the 10 - 100-yr events. The peak stage in the basin during the 500-yr flood would be produced by the Range Wash Storm, since 500-yr runoff events from the Interbasin and Spring Mountain Storms would overtop the diversion dike.

The starting water surface for the 10-year event was determined using normal depth. The basin stages at the time of the peak were used in the HEC-2 model as the starting water surfaces for the 50-year event (2121.5), 100-year event (2125.0), and 500-yr event (2129.0).

Return period	10	50	100	500
Wash Flow	2939	6751	8537	19217
NLVDB Inflow	2939	6751	8343	8343
Basin Pool elev.	2117.9	2130.5	2135.4	2137.3

Subreach 3 - NLVDB (299+02) to A Channel (1+50)

The water surface profile for Subreach 3 between NLVDB and the downstream terminus of the King Charles Channel at the A Channel was computed using several models. The reach from the Craig Road Bridge to the NLVDB was modeled as a subcritical/critical water surface profile. The water surface profile from the downstream terminus of the King Charles Channel to Craig Road Bridge was computed using both subcritical/critical and supercritical/critical flow regimes.

There are numerous locations within the wash upstream of Lone Mountain Road with substantial piles of rubble and debris, including auto bodies, concrete construction debris, tires, and urban trash. This debris was observed during each of the 3 NHC site

visits. There is a high probability that much of this debris would be mobilized during large flood events and potentially reduce the capacity of the existing flood control structures. The City of North Las Vegas responded to NHC's concerns by stating in a letter dated June 21, 1996 that:

> The section of the wash between Lone Mountain Road and the North Las Vegas Detention Basin is scheduled for cleaning and debris removal on a yearly basis. Our maintenance schedule indicates that these activities should occur within the next 60 days. For your reference in preparing your hydraulic model, I will provide you with a photograph of the wash after maintenance activities are complete.

During a site visit in December of 1997, the amount of debris and rubble in the wash appeared to have increased from the previous site visit in 1996. In general, the hydraulic models assume that the debris in the wash will not affect conveyance. However, the effects of debris were taken into account at section 184+62 and at Lone Mountain Bridge. (See discussion below.)

N Values used in Subreach 3

Concrete lined channel	n = 0.014
Developed overbanks (Primarily pavement areas, smooth earth, or sparse landscaping)	n= 0.03 to 0.035
Earth Channels (constructed)	n = 0.03
Unimproved Wash	n = 0.045
Industrial lots	n = 0.045
expansion coeff=0.3	
contraction coeff =0.1	

The hydraulic baseline was modified from the With Diversion Dike Condition to follow the historical wash between stations 267+00 and 299+02. HEC-2 model LN-50026 with the 100- and 500-yr profiles, reflects this alignment, however the HEC-2 model LNLVWO16 alignment for the 10- and 50-yr profiles is consistent with the With Diversion Dike Condition (these flows are assumed diverted through the basin).

Sta	Description
294+13	Cross sections obtained from 1996 Kenney aerial photogrammetry
268+45	A Manning's n of 0.045 was used for the wash from station 294+13 to the Lone Mountain Bridge.
263+83	Begin profile for 10- and 50-yr floods. Sections obtained from aerial
198+02	photogrammetry.
192+15	Sections cut from CNLV Topographic maps
-186+19	Sections represent topography at a large excavation in the wash

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

184+72
184+62

Sections represent channel constrictions caused by tailing's piles and concrete rubble pile in channel invert. The mounds and debris cause the flow to back up and water to break out between 18710 & 18472 during the 100 and 500 year flood events. The peak breakout flow for the 100 year event is 426 cfs and 2921 cfs for the 500 yr event. This flow leaves the channel at Losee and Azure. A pile of concrete construction debris (i.e. concrete junction boxes, manhole eccentric cones and bases) deposited on the upstream side of a dirt road (Azure) appears as a 2-3' mound in the wash invert on the CNLV topography maps. The cross sections used in the model reflect this pile of debris to the extent possible from available mapping.

Breakout flows calculations at Azure and Losee Rd., Station 185+00 compute normal depth of a rectangular channel at 1' depth for breakout Q

100 yr Q_{out} = 426 cfs
n = 0.045
s = 0.008 $^{ft}/_{ft}$
w = 150 → v = 2.9 fps, d = 1.0'
ss = 0

∴ End AO_1 Zone where breakout flow crosses over Losee & Azure and is unconfined laterally

500 yr

Q_{out} = 2,921 cfs
The CNLV Topographic maps were used to delineate the 500 yr flood plain. Downslope of the intersection of Losee & Azure the ground surface slopes at 1% to the southeast. The cross section normal to the direction of flow is relatively flat with out any significant channels. The breakout flow will likely spread to sheet flow until it is confined to 1-3' deep rills in the wash surface. A ridge shown on the CNLV topography confines the flow on the east side. The lateral extent of the 500 yr flood plain was approximated using normal depth calculations. Berms on the up-slope side of a golf course south of Ann Road cause some of the 500-year event to be pooled.

There is a high degree of uncertainty as to how the 2,921 cfs breaking out of the channel at Azure and Losee will be distributed in the wash - east of the main wash. A ridge approximately 750' to the east of Losee (shown on sheet 19 of the City of North Las Vegas topo) confines the eastern inundation limits to a 1300 ft ± corridor. Approximate depth and velocity is as follows

Rectangular channel
BW = 1300'

Q = 2921		depth = 0.8 ft
n = 0.045	→	vel = 2.8 fps
s = 0.01		

176+12 Section obtained by aerial photogrammetry.

170+58-165+46 These sections were obtained by aerial photogrammetry. The wash is composed of a partially constructed channel within the natural wash. We were provided with signed and approved rough grading plans for the Sunrise Park Inc., dated May 1996. During our December 1997 site visit, it appeared construction had been suspended. City officials informed NHC that the project had been stopped. At this time the section 165+46, obtained from aerial photogrammetry, was inserted back into the models and the Sunrise Park sections were removed. In April of 1998, following completion of the hydraulic modeling we were informed the plans for this section of channel were completed. Since incorporating these improvements would have required remodeling this subreach and would have delayed the submittal of the study, it was agreed with the Project Officer that the proposed improvements would not be included in the study.

Near section 170+58 there is significant debris scattered in the wash The debris includes a mound of tires approx 100'x50' appearing 1'-3' deep, plywood, on other urban debris. This debris was assumed to be removed as per the CNLV letter dated June 21, 1996.

156+67 The section was obtained from CNLV aerial topographic mapping. Upstream of this section is unfinished channel grading from the Sunrise Park Inc construction.

156+67-143+68 Drainage channel: rock side slopes and a native material bed. Downstream of this section are channel improvements consisting of rock side slopes and a native material bed. We were unable to obtain channel plans for these improvements, however the sections 156+67 through 143+68 reflect the channel geometry as of December 1997.

<u>100-year</u> - Split flow computation between 130+94 and 151+14

Excavation in the wash between section 151+14 and 143+68 causes flow to overtop the left overbank area and sheet flow along the wash west of the main channel within the wash. Although, the main channel within the wash downstream of section 143+68 is capable of conveying the entire 100-year flow of 8,109 cfs, there are not any prominent physical features to guide the overbank flow back into the channel between sections 143+68 and 130+94. The flow on the west floodplain downstream of section

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

143+68 is hydraulically disconnected from the water surface profile computed by HEC-2. Breakout flows along the west bank will result in shallow flooding to the right of the channel. Normal depth calculations were used to determine the depth and velocity of the flow in the area to the west of the wash channel.

Break out flow:

avg depth = 1 ft	at a width = 500'	
s = 0.005 $^{ft}/_{ft}$		
n = 0.045	normal depth =>	Q = 1164 cfs
		V = 2.3 fps

AO Zone calc. from 130+94 to 151+14

s = 0.005		
n = 0.045		
w = 450'	normal depth =>	1.1 ft
Q = 1164		v = 2.4 fps

This sheet flow will return to the channel near station 130+94 where it will be captured by a trench running perpendicular to the wash. Due to the uncertainty in predicting where the flow will reenter the channel the BFE's were calculated in HEC-2 using the entire 100 yr flow of 8109 cfs.

143+68 The channel narrows at this location upstream of a perpendicular trench in the wash. Cross section was obtained from CNLV aerial topographic mapping.

141+67-130+94 Channel incised in wash between these stations, native earth bed and bank. These sections were obtained by aerial photogrametry. 20' wide trench perpendicular to channel intercepts right overbank flows.

130+94 116+14 The main channel transitions from a 100' wide and 8-12' deep man made channel to the shallower wider wash.

The wash flows southeast across Losee between sections 116+14 and 9+29. The majority of the flow crosses at two low water crossings along Losee, refer to spot elevations on Sheet 7 of the Work Maps for low water crossings on road. The wash main channel intersects Losee Road approx 350' south of Washburn Road.

109+62-101+55 At section 101+155, La Madre Way cuts through a ridge in the wash and is a localized low spot on the left bank. Cross section 101+55 in the HEC-2 run shows overtopping along the right bank during the 100 yr flood. The amount of flow that would break out at this location is small since the computed overtopping depth is 0.1' and the width of the low point is approximately 40 ft.

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

These cross sections were obtained from aerial photogrammetry.

101+55-88-60

The 10 yr and 50 yr flows are conveyed to Lone Mountain Road bridge within the wash. A rainfall event upstream of the bridge occurring in the summer/fall of 1997 was estimated to have had a peak discharge of 200 to 400 cfs. This estimate was developed from the highwater marks left downstream at the Craig Road Culverts. During a site visit in December 1997 there was approximately 2-3 feet of deposition in the Lone Mountain inlet channel and bridge. Much of this deposition is a result of headcut erosion occurring immediately upstream of the concrete bridge inlet channel in a native earth transition to the wash. The slope of the wash before the event was approximately 1%, the earth transition was approximately 9%, and the concrete inlet channel is 1%. On the December 1997 visit, the slope in the now larger transition was estimated to be 4 to 6%, with several large headcut channels at the upstream end. The material deposited in the channel and bridge ranged in size from large gravels to cobbles. The larger material is not representative of the wash surface, but is evident in the banks of the eroding channels. This material is older alluvial deposits, and appears to be available in virtually unlimited supply if the headcutting process proceeds upstream to Losee Road.

The large volume of sediment deposited in the channel and bridge, during the summer/fall 1997 flood event raised the question: would the channel and bridge become blocked with sediment during the 10 and 50 yr flood events? To answer this question, the critical shear stress was calculated for a 5" cobble. It was assumed that 90% of the inflowing sediment to the channel had a nominal diameter of less than 5 inches. The critical shear was related to flow depth to determine if the flow depths in the channel and bridge were greater than the depth required to initiate motion in 90% of the inflowing particle sizes flowing into the channel and bridge section. Assuming a dimension less shear stress between 0.03 and 0.047 and energy slope through the bridge to be equal to the bed slope, 1%, the critical shear stress required to move a 5" particle ranges from 61.5 and 96.4 N/m. These critical shear stresses correspond to flow depths between 2 and 3.5 feet. This cursory analysis does not take into account the dynamics of the bed load matrix, hiding factors, changing transport capacities, or sediment continuity that would be required better estimate the sediment routing through the channel and bridge. However, it does provide a rough estimate that at flow depths greater than 3.5 feet deep the culvert would likely pass the sediment through the channel and bridge.

Using an HEC-RAS model of the reach between Lone Mountain and Craig Road produced for the **142 Acre Site at Losee Road and Craig Road LOMR**, the flow through the Lone Mountain Road Bridge was found to

become pressurized at flows greater than 4000 cfs. The bridge would be pressurized during a 100 and 500 yr floods of 8110 and 14939 cfs, respectively, with flow overtopping the road and breaking out over the left bank. Much of the bedload carried into the inlet channel by the 100 and 500 yr floods would be deposited in the channel and bridge, since the bridge would be capable of passing less than 50% of the flow, but 90 to 100% of the bedload mobilized by the 100 and 500 yr floods would be conveyed to the bridge inlet channel.

Based on the high supply of cobble sized material that would not be transported through the bridge under pressure flow conditions, the Lone Mountain Bridge was assumed blocked during 100 and 500 yr floods. Because the bridge remains in open channel flow conditions during the 50-year event, it was assumed that the inflowing load will be transported through the bridge under these conditions. Lone Mountain Road slopes to the east at approximately 1 to 3%. The 100 and 500 year flows would be backed up by the road and overtop the road from the Losee/Lone Mountain Intersection to approximately 1700 feet to the east along Lone Mountain Road. There would be a significant difference in energy head between the flow overtopping the bridge at Lone Mountain Road and overtopping Lone Mountain near Berg Street. The overtopping of Lone Mountain was modeled by cutting a section starting downstream of the left bank of section 9120 to the center of the bridge and then to the intersection of Losee and Lone Mountain Road. This section does not appear in the 10-50 yr HEC-2 model (LNLVW16O).

Flow splits at Lone Mountain Bridge

Lone Mountain Bridge is assumed to be completely blocked during the 100 and 500 without diversion scenarios. The flow split at the bridge was computed by partitioning cross sections 87+94, at the bridge, into areas where the flow would be conveyed in the right and left banks and in the channel. The ratio of the conveyance area of each partition with the total area was multiplied by the peak discharge.

100 year

Left floodplain
(8109 cfs) (57%) = 4622 cfs

Channel
(8109 cfs) (11%) = 892 cfs

Right floodplain
(8109 cfs) (32%) = 2595 cfs

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

Sheet flow computations for the left and right floodplains were based on normal depth computations.

Left bank normal depth computation downstream of Lone Mountain Road

Q = 4622 cfs
n = 0.03 side slope right = 0
s = 0.008 side slope left = 175
bw = 650'

=> d = 1.3', v = 4.8 fps ∴ AO depth 1 ft
a slight ridge running north to south confines the flow in the left floodplain on the east side and guides the flow back to the channel downstream of cross section 6828 where the flow starts to back up and break out as a result of the Craig Road culverts.

Right bank normal depth computation downstream of Lone Mountain Road

Lone Mnt Rd to 350' d/s of LMR
n = 0.03
s = 0.008
bw = 400
Q = 2594 cfs => d = 1.3 ft, v = 5.1 ft

350' d/s of LMR to 650' d/s of LMR
n = 0.03
s = 0.008
bw = 600
Q = 2594 cfs => d = 1.0 ft, v = 4.4 fps

> 650' d/s of LMR
n = 0.03
s = 0.008
bw = 900
Q = 2594 cfs => d=0.77, v = 3.7 fps, E ≈ 1.0
End AO zone depth 1'
Losee Road confines the right floodplain flow on the west side. The flow will disperse and have an energy depth less than 1' and/or re-enter the channel.

91+20 Upstream end of concrete inlet channel to Lone Mountain Road. The transition from the wash to the inlet channel consists of an unlined 9% flared slope to the wash that has been head cut into several gullies to a slope between 4% & 6%, as described above.

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

88+60 Station Equation 88+60 ahead = 88+34.5 back downstream end of concrete inlet channel upstream end of Lone Mountain Road Bridge. Section used for 10 and 50 yr HEC-2 model (LNLVWO16). Section not included in 100-500 yr flood model (LN-50026).

88+05 Left bank to Lone Mountain Road (cross section station 300) obtained from CNLV topo, cross section station 300 to Losee obtained from BSI grading plans. Section not included in 10-50 yr flood model (LNLVWO16). Section used for 100 and 500 yr HEC-2 model (LN-50026).

87+54 Downstream end of Lone Mountain Bridge begin transition to trapezoidal channel (rock side slopes & native material bottom) channel "n"=0.03 overbank n=0.03

86+73-60+92 Trapezoidal channel rock side slopes native material bottom with rock grade control structures at 200' intervals

59+74 Upstream end of Craig Road Culverts (7-8'x8.5' RCB). The culvert has adequate capacity to convey the 10 - 50 year flood events. The 100 and 500 yr HEC-2 model, LN-50026, ends at this station. The starting water surface elevation for the 100 and 500 yr model was determined by balancing the flow through the Craig Road culverts, the flow over Craig Road at the culvert and the flow over Craig near the intersection of Craig and Frehner Road with the total 100 yr flow of 8109 cfs for a given water surface elevation (see Table 1). The rating curve for the culvert was computed using HY8. The low points along Craig Road occur near the intersection of Craig and Frehner roads, approximately 1923.6 feet NGVD 29 and near the center of the Craig Culvert, approximately 1924 feet NGVD 29. Road profiles and low points were obtained from the BSI Site Grading Plan and converted from NAVD 88 to NGVD 29 by subtracting 2.4'. The water over topping the road at Craig and Frehner during the 500 year event continues south over Craig Road and is contained to the East by the UPRR embankment. Flow overtopping Craig Road near the culvert is split to the west and east by the concrete walls of the King Charles Diversion Channel. Approximately 491cfs flows to the west into the industrial park between bordered on the west by Losee Road and on the east by the King Charles Diversion Channel.

The computed flow splits

	WSEL	Craig culvert	Left bank	Right bank
100-yr	1925.6	6307	1312	491
500-yr	1926.2	6638	4858	3444

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

On the south side of Craig Road, west of the RC channel, are two 80' x 250' buildings. There are three ~35' alleys on either end of the ends of the buildings and a 35' alley between them.

Downstream of the Craig Road commercial site, the flow is bounded on the southeast by a concrete block wall on the east side of Frehner. Split flow to the right of King Charles Channel downstream of Craig Road. The UPRR bridge on the KC Channel causes water to back up and flow over the right bank upstream of the UPRR bridge. This area between Frehner and the UPRR embankment is primarily industrial businesses with 1/3 of the lot area used for storage and work areas. Chainlink fences at the borders of those businesses, in addition to stored materials will serve to disperse the flow and increase the probability of uniform shallow flooding.

n = 0.045
bw =2/3 (450) = 300
Q = 1021 cfs => d = 1.0 ft, v = 3.3 fps

The 491 cfs passing through the Craig Road commercial site will flow along Frehner and combine with the weir flow of 1021 cfs near Losee and Frehner. Any attenuation that might occur in these industrial areas is ignored. The resulting discharge between Losee and the railroad embankment is 1512 cfs.

n = 0.045
bw = 2/3 (550) = 370
Q = 1512 cfs => d = 1.1 ft, v = 3.6 fps

This flow will enter the "A" channel between Losee Road and the UPRR embankment.

KING CHARLES CHANNEL

The water surface profile for the 10-500 year flood events in the King Charles Channel were modeled for both the supercritical and subcritical flow regimes. The HEC-2 model LNLVWO16 was used to compute the 10-50 yr subcritical profiles, KGSBW02 was used to compute the 100-500 yr subcritical profile and KGSCW02 was used to compute the 10-500 yr supercritical profiles. Cross section geometry for the King Charles Channel was obtained from the King Charles Diversion Channel from the N-Channel As-built plans.

The flow in the King Charles Channel downstream of the Craig Road culvert changes regime from supercritical to subcritical, and from subcritical to supercritical. The details of the composite profiles are shown on Table 2. Froude numbers less than 1.2 were considered to be subject to a hydraulic jump. This assumption is based on COE EM1601

Hydraulic Design of Flood Control Channels (pg 11) which states that Froude numbers between 0.86 and 1.13 are unstable. Due to the uncertainties in the modeling of the channel, a Froude number of 1.2 was used instead of 1.13 to determine the lower limit of stable supercritical flow. The flow regime through the channel was determined to be supercritical if it met the following criteria:

1. Froude number >1.2
2. Downstream wsel < than upstream wsel

If both of the criteria listed above were not met than the water surface was assumed to be calculated by the subcritical model. Resulting in a subcritical or critical water surface elevation.

58+51
51+05 The KCC starts at 58+52 in a 60 foot wide concrete rectangular section downstream of the Craig Road culvert and extends down to station 51+05. The rectangular section narrows from a bottom width of 60 ft at the culvert to a width of 35 ft at section 51+05. Invert slope is 0.0065 ft/ft.

51+05
50+05 Concrete transition from rectangular channel to a trapezoidal channel at section 50+05, bottom width 15 ft, side slopes 2H:1V. The invert slope changes at section 51+05 to 0.02 ft/ft.

50+05
43+60 Concrete trapezoidal channel from 50+05 to 43+60. The invert slope changes at section 50+05 from 0.02 ft/ft to 0.0082 ft/ft. This grade of 0.0082 ft/ft extends to 41+15. A maintenance access ramp between stations 49+20 and 47+81 was not included in the models. Instead a uniform trapezoidal channel was modeled.

43+60
42+47 The channel transitions from a trapezoidal channel to a rectangular channel at the upstream face of the UPRR Bridge, station 42+46. As-built plans for the bridge were not available. Field Surveys verified the invert and soffit elevations at the bridge. The bridge was modeled using the normal bridge method. The normal bridge method accounts for the losses occurring in the 10 and 50 yr floods due to pier obstructions and increased wetted perimeter. The 100 and 500 yr flood hydraulics at the bridge become more complicated with a portion of the water that flows over Craig Road reentering the channel upstream of the UPRR bridge. In addition to the water reentering from the left bank, water is leaving the channel along the right bank and flowing into the adjacent industrial park. Rating curves for the flow through the UPRR bridge (developed using the Special Bridge routine in HEC-2), out of the channel along the right bank (developed using a standard weir equation along the right channel bank), and out of the UPRR culvert northeast of the bridge were developed. A water surface elevation was calculated by balancing the combined flow through the outlets at a common water surface elevation with the total flow

upstream of the outlets (see Table 3). The water surface elevation computed from the flow balance for the 500 yr flood was 1912.7. The water surface computed at the bridge using the normal bridge routine in HEC-2 was 1912.0. This 0.7' difference in water surface elevations near the bridge opening is acceptable due to the uncertainty of the flow characteristics at a discharge far above the capacity of the channel system.

42+47
41+88

The bridge is skewed to the flow by 35° between sections 42+47 and 41+88. The length of the bridge perpendicular to the railroad tracks is 33 ft. The effective length of the bridge, taking into account the distance between the first point along the channel centerline where the flow is directly affected by the upstream face of the bridge to the last point along the channel centerline where the flow is directly affected by the flow, is closer to 57 ft. The upstream and downstream bridge sections were spaced 57 ft apart to account for the skew of the bridge and cut perpendicular to the channel instead of using a skew factor in the HEC-2 model at the bridge.

The contraction and expansion coefficients were changed to 0.3 and 0.5, respectively, through the bridge sections. The discharge was reduced at section 42+46 from 6307 cfs to 5779 cfs to account for the breakout flows.

41+15
38+23

The flow at this section is divided between the King Charles Channel, and the N Channel. The division of flow between the King Charles Channel and the N Channel is based the ratio of the channel areas to the total channel area, resulting in 80% of the flow diverted to the King Charles Channel and 20% of the flow diverted into the N-Channel. The inlet at the N Channel has a maximum capacity of approximately 1248 cfs.

N-Channel Normal Depth Calculations

N-Channel entrance

w = 4.75
h = 10.5
s = 0.00576
n = 0.014
Q = 624
v = 12.5

A normal depth computation using the cross section at the face of the "N" channel was used to determine the maximum conveyance into the "N" channel.

Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

Q = 1248 cfs max conveyance

Return period	King Charles Channel u/s (cfs)	N-Channel (cfs)	King Charles Channel d/s (cfs)
10	1281	256	1025
50	2183	437	1746
100	5779	1156	4623
500	7081	1248*	5833

*since 20% of 500 w/o diversion 1416 cfs > 1248 cfs maximum, "N" Channel conveyance

A transition along the side slope of the right bank begins at section 41+15. The vertical bank changes to a 1.5H:1V side slope at section 40+60. The left bank remains vertical. The invert slope changes from 0.0082 ft/ft upstream of section 41+16 to 0.0033 ft/ft downstream of this section. The channel curves at a centerline radius of 150' to the south. The effects of superelevation were neglected. Under extreme hydraulic conditions during the 500 yr flood, transverse waves combined with superelevation may cause minor overtopping along the left bank through the curve. It is unlikely that the volume and depth of the overtopping would be sufficient to cause significant flooding. However, the area to the left of the channel was designated a shaded X Zone due to the upstream flow split through the UPRR culverts that would travel along Donovan Way (see discussion of split flow to the right of King Charles Channel).

38+23
37+24 The left bank transitions from a vertical slope to a 1.5H:1V side slope at section 37+24.

37+24
5+44 The channel between section 37+24 and 5+44 is a uniform trapezoidal channel with a bottom width of 20 ft +/- and side slopes of 1.5H:1V. A concrete trapezoidal channel drains into the KCC at station 22+50. This channel is intended to convey flow from the industrial complex to the west underneath the UPRR embankment through 2 - 3ft x 6ft culverts. Flapgates on downstream side of these culverts appeared to be stuck in an almost closed position during NHC's December 1997 field visit. On the upstream side of the culvert was half filled with sediment and had a tree with a 4" diameter trunk growing in the channel. Inflow from the culverts was neglected in the analysis.

5+44 The channel transitions from a trapezoidal channel at station 5+44 to a rectangular channel with a bottom width of 35 ft at section 4+44. The rectangular section continues to section 2+43 where a splitter wall divides the channel into to channels of equal bottom width. The HEC-2 model end at section 1+50. Downstream of this section the uniform rectangular

channel ends at station 0+88 the KCC and A Channel confluence. The stationing continues downstream to station 0+00 and the upstream face of the Interstate 15 bridge.

The starting water surface elevations used in the model at station 1+50 were calculated in HEC-2 using the slope area routine with the assumption that the bed slope approximated the energy slope at this section.

The Project Officer instructed NHC to use the Ensign and Buckley Preliminary LMMP to obtain the 100 yr backwater elevations from the A Channel (1892.9 ft). We were instructed to estimate the 10, 50, and 500 yr backwater elevations by using the discharges from the Lower Central Valley Storm in the Clark County Regional Flood Control District **Las Vegas Valley Flood Insurance Study Hydrology Report**. Normal depth was computed at station 0+00 for these discharges and added to the invert elevation at 0+00, 1885.4 ft. The Manning's N used in the calculations was calculated by applying the normal depth calculation for the known 100 yr water surface and discharge used in the Ensign and Buckley Preliminary LMMP and determining the N.

A Channel Normal Depth Calculations:
ss_L=2H:1V invert el.= 1885.4 ft
ss_R=0H:1V invert s= 0.0033 ft/ft
BW=48 ft n= 0.017

Return Period	LCVS Q	Depth	WSEL	Backwater to Station
10	2160	3.8	1889.2	1+50
50	5120	6.4	1891.8	4+50
100	6730	7.5	1892.9	0+00
500	12400	10.8	1896.2	7+00

The computed water surface elevations from the 10 - 500 yr events in the A Channel back up into the KCC and set the maximum water surface elevations for the 10, 50, and 500 year recurrence intervals as listed above.

500 Year Breakout Flows From Station Ann Road to Craig Road

The 2921 cfs breakout from the 500 yr flood will be distributed in a series of small washes across a width of approximately 1300' and an average depth of 0.8 ft upstream of Ann Road. A berm running perpendicular to the wash south of Ann Road will act to pond some of the water and force the rest toward Losee Road. The flow will be conveyed in a corridor with an approximate width of 1400' between the main wash channel and a Golf Course east of Losee. Downstream

of Washburn Road, the wash surface slopes southeasterly. Sheet flow from the 500 yr breakout flow will spread out, potentially covering an area that extends to the UPRR embankment. The inundation limits for the extent of the 500 yr breakout flow were estimated using USGS Las Vegas NE and Valley Quadrangle maps. Sheet flows will be distributed in multiple channels and new channels would probably form. The unpredictable nature of the flow paths potentially exposes the entire area shown on the work maps to shallow flooding.

100 Year Breakout Flows Downstream of Craig Road East of the King Charles Channel.

Approximately 1312 cfs during the 100 yr flood was calculated to overtop Craig Road east of the KCC. This water flows into a vacant triangular parcel bounded by the King Charles Channel on the west and the UPRR embankment to the southeast. This area has remnant channels of the Upper Las Vegas Wash which flow toward 2 - 5.5 ft x 12 ft culverts under the UPRR embankment. These culverts were computed to have a conveyance of 819 cfs at a water surface elevation of 1912.7 ft. The remaining 493 cfs would flow to the south west back into the channel upstream of the UPRR bridge.

The water flowing through the UPRR culverts would be conveyed in a trapezoidal earth channel between Donovan Road and the UPRR embankment and has a bottom width of 30 ft +/- , side slopes 3H:1V, and an average depth of 4 to 5 feet deep. The invert slope is approximately 0.005 ft/ft. The water would breakout of this channel upstream of the Donovan N Channel crossing with much of the flow entering the N Channel. A portion of the flow could cross the N Channel in Donovan Road, but this flow would be too small to result in flooding depths greater than 1 foot for the 100-year condition.

N CHANNEL

The N Channel conveys approximately 20% of the flow for the 10-500 yr floods from the King Charles channel upstream of station 41+15 on the KCC alignment to Interstate 15, the study limit. This reach was both a subcritical/critical and supercritical/critical water surface profile was calculated using HEC-2. The subcritical/critical HEC-2 model defaulted to critical depth for the N Channel reach at a n of 0.14 the n was increased to 0.025 before the a subcritical water surface profile was computed. However, a couple of cross section were not able to converge on a solution. Those sections that did converge on a subcritical solution had unstable Froude numbers between 0.85 and 0.97. The supercritical water surface profile was stable for the entire channel reach for the 10-50 year events. The computed profile for the 100 and 500 yr floods was also stable when the combined flow from across Donovan and from the diversion was entered at the upstream end of the model. However, when the flow across

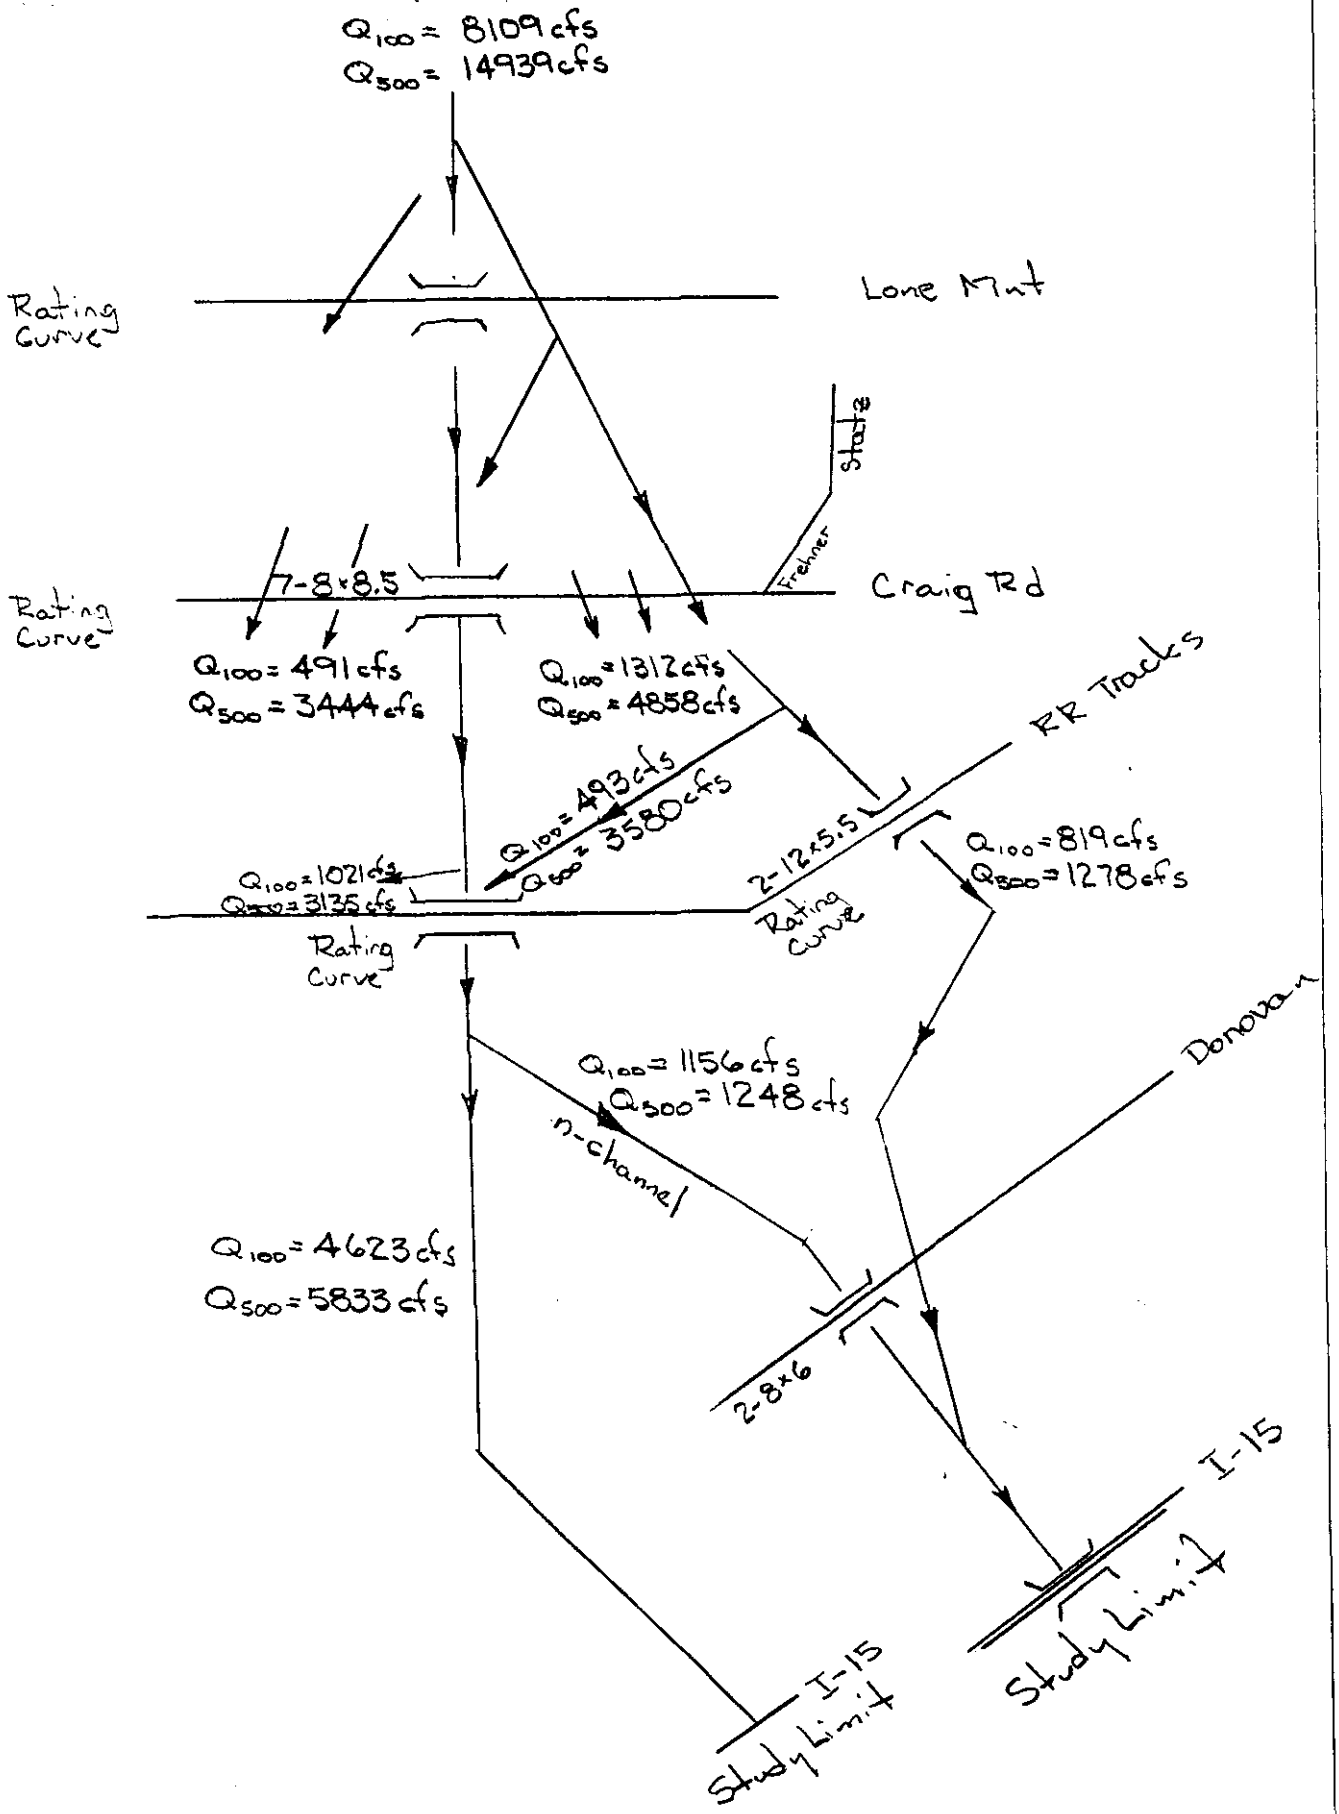
Without North Las Vegas Detention Basin Diversion Dike - Hydraulic Notes

Donovan was inserted between sections 5+71 and 4+46, the model calculated critical depth at sections 4+96 and 4+46. The increased discharges at these sections is likely the reason for the inability of the model to converge on a supercritical solution. Therefore the supercritical/critical water surface profile with overtopping between 5+71 and 4+46, channel n=0.017 in locations with side flow entering and channel n = 0.014 for other areas, was considered the most representative model of the hydraulic conditions.

As is standard practice in computing a supercritical water surface profile using HEC-2 model the fields for the contraction and expansion coefficients were swapped. The starting water surface for the model was set using the water surface elevation in the KCC at the diversion, section 41+15.

7+08
6+38 The N Channel branches off the KCC through a 9.5 ft wide concrete lined rectangular channel and has a 10" wall running down the center of channel. The channel widens from 9.5 ft to 16 ft at the upstream side of Donovan Way, station 6+38. The channel has a constant slope of 0.0058 between station 7+08 to the downstream study limit at station 0+00

6+38 The N Channel passes under Donovan Way in 2 - 6 ft x 8 ft reinforced concrete box culverts. The soffit and invert elevations of these culverts were verified by field surveys. The culvert was modeled using the Normal Bridge Routine in HEC-2. Contraction and Expansion coefficients of 0.3 and 0.5, respectively, were used at the culvert. The contraction and expansion coefficients could have been remained 0.1 and 0.3, respectively, since the entire reach of channel from the diversion to the culvert is a gradual transition. However, a conservative approach of increasing the coefficients was modeled.



5+72
5+46 The channel transitions from the box culverts to a trapezoidal channel with a 10 ft bottom, 2H:1V side slopes, and a depth of 7 ft.

The 100 yr flow, 819 cfs, entering the N Channel from flow overtopping Donovan Way was added in 273 cfs increments to the model between sections 5+72 and 5+46, 5+46 and 4+96, and 4+96 and 4+46. The channel roughness was increased by 20% from 0.014 to 0.017 between sections 5+46 and 0+25. This increase was added to account for the turbulence created by flow entering the channel as shallow flow. No increase in the 10-100 yr floods were made since there was not any flow entering the channel at this point.

5+46
0+25 Uniform trapezoidal concrete lined channel.

0+25 Transition from trapezoidal channel to 2 - 6 ft x 12 ft concrete box culverts at station 0+00. Section 0+00, the upstream face of the Interstate 15 culvert, represents the downstream study limit.

Test 1: If supercritical F > 1.2, then go to Test 2 otherwise use subcritical water surface elevation

Test 2: If resulting water surface from Test 1 > downstream water surface the use supercritical watersurface otherwise use subcritical water surface elevation

Unstable Flow 0.86<F<1.13, Supercritical run assumed unstable if less than 1.2

SUMMARY OF ERRORS AND SPECIAL NOTES

NOTE SECNO= 5973.000 PROFILE= 1 WSEL BASED ON X5 CARD
NOTE SECNO= 5973.000 PROFILE= 2 WSEL BASED ON X5 CARD

WARNING SECNO= 6092.000 PROFILE= 1 CONVEYANCE CHANGE OUTSIDE ACCEPTABLE RANGE
WARNING SECNO= 6092.000 PROFILE= 2 CONVEYANCE CHANGE OUTSIDE ACCEPTABLE RANGE

WARNING SECNO= 6370.000 PROFILE= 1 CONVEYANCE CHANGE OUTSIDE ACCEPTABLE RANGE
CAUTION SECNO= 6370.000 PROFILE= 2 CRITICAL DEPTH ASSUMED
CAUTION SECNO= 6370.000 PROFILE= 2 PROBABLE MINIMUM SPECIFIC ENERGY
CAUTION SECNO= 6370.000 PROFILE= 2 20 TRIALS ATTEMPTED TO BALANCE WSEL

CAUTION SECNO= 6828.000 PROFILE= 2 CRITICAL DEPTH ASSUMED
CAUTION SECNO= 6828.000 PROFILE= 2 PROBABLE MINIMUM SPECIFIC ENERGY
CAUTION SECNO= 6828.000 PROFILE= 2 20 TRIALS ATTEMPTED TO BALANCE WSEL

CAUTION SECNO= 7265.000 PROFILE= 2 CRITICAL DEPTH ASSUMED
CAUTION SECNO= 7265.000 PROFILE= 2 PROBABLE MINIMUM SPECIFIC ENERGY
CAUTION SECNO= 7265.000 PROFILE= 2 20 TRIALS ATTEMPTED TO BALANCE WSEL

CAUTION SECNO= 7730.000 PROFILE= 2 CRITICAL DEPTH ASSUMED
CAUTION SECNO= 7730.000 PROFILE= 2 PROBABLE MINIMUM SPECIFIC ENERGY
CAUTION SECNO= 7730.000 PROFILE= 2 20 TRIALS ATTEMPTED TO BALANCE WSEL

CAUTION SECNO= 8323.000 PROFILE= 2 CRITICAL DEPTH ASSUMED
CAUTION SECNO= 8323.000 PROFILE= 2 PROBABLE MINIMUM SPECIFIC ENERGY
CAUTION SECNO= 8323.000 PROFILE= 2 20 TRIALS ATTEMPTED TO BALANCE WSEL

CAUTION SECNO= 8794.000 PROFILE= 1 CRITICAL DEPTH ASSUMED
CAUTION SECNO= 8794.000 PROFILE= 1 PROBABLE MINIMUM SPECIFIC ENERGY
CAUTION SECNO= 8794.000 PROFILE= 1 20 TRIALS ATTEMPTED TO BALANCE WSEL

Introduction to Volume 5

This volume of the TSDN contains study report data and flood profiles. The study was completed for two cases due to uncertainty regarding the performance of the North Las Vegas Detention Basin Diversion Dike during a major flood event. This volume contains the report data and profiles for the '**With North Las Vegas Detention Basin Diversion Dike**' case. Volume 6 contains similar data for the "Without North Las Vegas Detention Basin Diversion Dike'. A discussion of the evaluation of the diversion dike and other flood control structures in the study area is included in Volume 2.

Flood Insurance Study

Clark County, Nevada

With NLVDB Diversion Dike

1.0 INTRODUCTION

1.1 Purpose of Study

Community Name: City of North Las Vegas; City of Las Vegas; Unincorporated Areas of Clark County
County: Clark County
State: Nevada

1.2 Authority and Acknowledgments

Study Contractor: Northwest Hydraulic Consultants, Inc.
*Subcontracto*r: Kenney Aerial Mapping (Mapping and Surveying)
Completion Date: April, 1998

Provider of Base Map: Kenney Aerial Mapping, Inc

Base Map Compilation Source: Kenney Aerial Mapping, Inc.
Base Map Compilation Scale: 1:4800
Base Map Compilation Date: August, 1996

Coordinate System: State Plane
Projection: State Plane
Datum: NGVD 1929

Has base map source been modified? Yes

If so, how and where: Corporate limits, section lines, and streets were added to base map drawing files from information provided by the City of Las Vegas and the City of North Las Vegas from community GIS mapping.

Any restrictions on the release of base map data?

No

If yes, what restrictions apply?

1.3 Coordination

Initial Consultation and Coordination Officer's (CCO) meeting date:

Wednesday, September 7, 1994

List of attendees and agencies represented at the initial CCO meeting:

Leslie K. Sakumoto, P.E. - FEMA Project Officer
Randy Tarr - City of North Las Vegas
Kevin Eubanks - Clark County Regional Flood Control District
Tom Chiatovich - City of Las Vegas
Bob Murnane - City of North Las Vegas
Phu Simpson - Clark County
Bob MacArthur, Northwest Hydraulic Consultants
Ed Wallace, Northwest Hydraulic Consultants

Intermediate CCO meeting data and attendees (if applicable):

Not applicable.

List of contacts made for the purpose of acquiring information:

Flooding sources requiring detailed study were discussed at the initial community meeting on September 7, 1994 involving representatives from FEMA, Clark County Regional Flood Control District, Clark County, City of North Las Vegas, and City of Las Vegas. Additional contacts were made with each of these agencies during the course of the study to obtain information. Additional contacts for the purpose of obtaining information were made with the US Geological Survey, Desert Research Institute, and FEMA's LMMP contractor, Ensign & Buckley Consulting Engineers.

The study contract was executed on September 25, 1995, and the first site visit and informational meetings were held on September 27 and 28, 1995. Separate meetings were held with the flood control district and each of the three communities in the study area to research available hydrologic and hydraulic reports, design documents for flood control facilities, as-built plans for bridges and other infrastructure, and available topographic mapping and aerial photography. A second site visit for the purpose of geomorphic reconnaissance was conducted on December 6 and 7, 1995. A meeting was held with Clark

County Regional Flood Control District at this time to discuss available information for the West Range Wash Diversion Dike, North Las Vegas Detention Basin and Diversion Dike, and Upper Las Vegas Detention Basin and Interception Berm; key hydrologic studies and precipitation analysis by the Corps of Engineers and NOAA; and existing sedimentation analyses for the diversion facilities.

The review of information provided by FEMA and the communities revealed gaps in the information regarding the design of the flood control facilities in the project area, including the two detention basins and three diversion dikes in the upper portion of the study area. A second site visit and meetings with Clark County Regional Flood Control District and the City of North Las Vegas were conducted on April 17 and 18, 1996. Additional information was obtained at these meetings, including review of microfiche files for the King Charles Channel, N Channel, and two bridges across Upper Las Vegas Wash. Blueline plans for these facilities were provided by the City of North Las Vegas on May 29, 1996.

Following the site review and initial hydraulic analysis, the study contractor requested additional information from the City of North Las Vegas regarding the status of the Sunrise Memorial Park development project and the control of debris in the Upper Las Vegas Wash channel. The City of North Las Vegas provided additional information in a letter dated June 21, 1996, advising the study contractor to consider the planned channel improvements at Sunrise Memorial Park in the hydraulic analysis, and that debris in the Upper Las Vegas Wash is scheduled for annual cleanup.

On August 13, 1996 the study contractor conducted a meeting with FEMA's project officer to discuss the results of preliminary hydrologic and hydraulic analysis. At this meeting, concerns were raised regarding the adequacy of available information in assessing the performance of the three diversion structures in the upper portion of the study area. The study contractor submitted preliminary hydrology and hydraulic information to FEMA on August 29, 1996 relating to these structures. In a September 12 conference call with representatives of FEMA, the study contractor was directed to assume that the Upper Las Vegas Wash Interception Berm would perform adequately in containing the base flood. It was agreed in this meeting that adequate information was not available to assess the performance of the West Range Wash Diversion Dike or the North Las Vegas Detention Basin Diversion Dike.

FEMA requested additional information from the Clark County Regional Flood Control District in a letter dated September 5, 1996, and subsequently notified the District on November 17, 1996 that work on the study had been suspended pending review of additional information on the West Range Wash Diversion

Dike. FEMA's Technical Evaluation Contractor (TEC) also began research into review documentation for the North Las Vegas Detention Basin Diversion Dike. FEMA issued a Letter of Map Revision for the West Range Wash Diversion Dike on January 28, 1997, but FEMA's research (concluded in April 1997) failed to reveal adequate information regarding performance of the North Las Vegas Diversion Dike if subjected to current estimates of the 100-year discharge.

The study contractor summarized the changes in estimated 100-year discharges and concerns regarding performance of the North Las Vegas Diversion Dike in an April 28, 1997 letter to FEMA, and FEMA advised the Clark County Regional Flood Control District of the situation in a May 5, 1997 letter. The Clark County Regional Flood Control District advised FEMA in a June 26, 1997 letter that the District agreed that the impacts of sediment on the structure, and the stability of the structure if overtopped warranted further consideration. The District undertook an independent evaluation of the diversion dike, and provided a report summarizing the results dated February 25, 1998.

To avoid delay in the completion of the study, the study contractor was directed by FEMA to complete hydraulic analysis of independent study cases with and without the North Las Vegas Detention Basin Diversion Dike.

The study contractor conducted a meeting with FEMA on December 11, 1997 and received information regarding a November 20 , 1997 LOMR issued in the study area between Lone Mountain Road and Craig Road. The study contractor conducted a site visit on December 13, 1997 to verify the conditions in the area of the LOMR and the remainder of the study area.

The study contractor met with the FEMA project officer on March 19,1998 to review the results of revised hydraulic analysis including the two cases with and without the North Las Vegas Detention Basin Diversion Dike, and the changes associated with the LOMR.

2.0 AREA STUDIED

2.1 Scope of Study

Note areas excluded from study, as well as areas of extraterritorial jurisdiction:

The study area includes the areas potentially subject to flooding from Upper Las Vegas Wash upstream of Interstate 15, including portions of the City of North Las Vegas, the City of Las Vegas, and unincorporated areas of Clark County. The study area's upstream (northwest) end is the upper end of the Upper Las Vegas

Wash Interception Berm in Section 4, Range 60 East, Township 19 South in the City of Las Vegas. It extends from this point eastward to the North Las Vegas Detention Basin in the City of North Las Vegas in Section 14, Range 61 East, Township 19 South, thence southward through portions of Clark County and the City of North Las Vegas to Interstate 15 near Gowan Road in Section 11, Range 61 East, Township 20 South. The study area excludes the areas southeast of Interstate 15; northwest of the North Las Vegas Detention Basin along the West Range Wash Diversion Channel; and north of the Upper Las Vegas Wash and Upper Las Vegas Wash Interception Berm channels.

List the flooding sources studied in detail (detailed study streams should be listed in the same order as they appear in profiles). If they are also partially studied by approximate methods, provide the limits of detailed study:

The flooding source studied in detail is the portion of Las Vegas Wash generally known as Upper Las Vegas Wash, located northwest of Interstate 15, including the following channel segments as referred to in the Clark County Regional Flood Control District August 1991 Master Plan Update of the Las Vegas Valley (Reference 1):

Upper Las Vegas Wash - King Charles Channel
Upper Las Vegas Wash
"N" Channel Diversion

List the flooding sources studied by approximate methods:

None

If applicable, discuss streams on which study was terminated where the 100-year floodplain permanently narrowed to less than 200 feet wide or for which detailed study was ended where the drainage area was less than 1 square mile:

None

2.2 Community Description

Provide a general description of the community's location within the county and state:

Clark County is located in the southern tip of Nevada. The greater Las Vegas metropolitan area, including the City of Las Vegas, City of North Las Vegas, and development within the unincorporated areas of Clark County, is located in the

central part of Clark County, approximately 20 miles west of Lake Mead. The study area is located in the northern portion of the Las Vegas metropolitan area.

List surrounding communities and their locations with respect to the subject community:

Surrounding communities include the town of East Las Vegas, approximately 10 miles southeast; the City of Henderson, approximately 15 miles southeast; and Boulder City, approximately 25 miles southeast.

List other nearby large cities and their locations:

Las Vegas is located approximately 250 miles northeast of Los Angeles, California; 360 miles southwest of Salt Lake City, Utah; and 340 miles southeast of Reno, Nevada.

Briefly describe the community. This description may include patterns of residential and commercial development; the extent and nature of floodplain development; natural features that affect flood hazards in the community; and sufficient description of climatic, physiographic, and land use features to support the discussion of flood problems that follows (Section 2.3).

The topographic features of Clark County are generally typical of the Basin and Range physiographic province, with north-south trending ranges. Las Vegas Valley cuts diagonally across the county, following a line of geologic deformation indicated by bending of the north-south trending ranges. Major ranges in the area include the Spring Mountain Range to the west, and the Sheep Mountain Range and Las Vegas Range to the north. The elevations of Las Vegas Valley are between approximately 3000 feet and 1800 feet (National Geodetic Vertical Datum, NGVD), and elevations of peaks in the surrounding ranges reach up to nearly 12,000 feet in the Spring Mountain Range and 10,000 feet in the Sheep Mountain Range. A series of large, coalescing alluvial fans are located along the margins of the upper portion of the valley at the base of the ranges. Much of the upper Las Vegas Valley floor is comprised of fine-grained lacustrine sediments. Marginal areas of the upper valley, and the lower Las Vegas Valley are covered by alluvial deposits. (References 2, 3).

The climate is arid to semi-arid, characterized by infrequent rainfall, low humidity, and wide extremes in daily temperatures. Annual precipitation in the area is strongly correlated to elevation, but intense cloudburst storms are possible in all areas of the Las Vegas Valley and surrounding ranges. The Las Vegas Valley receives an average annual rainfall of approximately 4 inches, and the higher elevations in the county receive up to 20 inches. Precipitation varies

greatly in any location from year to year due to local cloudburst events. The average annual temperature is approximately 66^0 F, with average daily maximums in the high 70's and average daily minimums in the mid 50's. Daily maximum temperatures usually exceed 100^0 F in the summer in the lower valley, and daily minimum temperatures drop below 20^0 F in the mountain ranges in the winter.

Vegetation is strongly zoned by elevation, with little or no vegetation on the playas, and sparse vegetation in the lower valleys. Species in the lower valleys are generally phreatophytes. Creosote bush, saltbrush, and rabbitbrush are common on the alluvial slopes, and Joshua trees, Spanish bayonet, small cacti, and blackrush grow on the middle portions of the fans. Above approximately 4,500 feet there are wooded areas of pinion and juniper (Reference 3).

The developed area of Clark County is concentrated in the Las Vegas Valley. Growth has been extremely rapid over the past 60 to 70 years, increasing from less than 5,000 in 1920 to approximately 600,000 in 1986. The current population is approximately 1.1 million. A large portion of the population is located in unincorporated areas of Las Vegas Valley. The developed area is located primarily in the lower portions of Las Vegas Valley, and is subject to runoff concentrated in the lower valley from a large surrounding geographic area. Development in the study area along Upper Las Vegas Wash, King Charles Channel, and "N" Channel includes low density residential, commercial, and industrial development. Extensive additional development, especially commercial and industrial development in North Las Vegas, is planned in the near future. This development is planned within the area formerly mapped within the 100-year flood hazard zone by FEMA in 1995 (Reference 4).

In addition to the permanent population, a large visitor population is present in the Las Vegas Valley throughout the year. The visitor population is generated primarily by the gaming and entertainment industries, which are a prime element in the County's economy.

2.3 Principal Flood Problems

Include the discharges and recurrence intervals of major floods:

Reports of flooding in the Las Vegas area date back almost 100 years. The U.S. Soil Conservation Service reviewed historical flooding in a report entitled History of Flooding, Clark County, Nevada 1905-1975 (Reference 5). This report documented 184 flood events that resulted in damages to private property and public facilities. Since 1960, the Las Vegas area has experienced at least seven floods that caused damages in excess of one million dollars, and the loss of over 22 lives in nine separate flash flood events (Reference 6).

The largest recorded flood on Las Vegas Wash occurred on July 3, 1976, when 12,000 cfs was measured at the USGS gaging station located upstream of Las Vegas Boulevard north of Las Vegas. The next largest events occurred on May 31, 1973 (1,640 cfs) , and September 25, 1967 (1,170 cfs). Although recurrence intervals for these events have previously been estimated by others (Reference 4), the construction of flood control facilities in the upper portion of the study area have altered flood flow paths and added flood storage to the extent that these estimates have little bearing on current recurrence intervals and flood discharges.

Give the location (city and state) of all stream gages for studied streams:

USGS Gages 09419648 (Las Vegas Wash above Detention Basin near North Las Vegas) and 09419650 (Las Vegas Wash at North Las Vegas) were discontinued in 1993 an 1978, respectively. There are no known active gaging stations on the studied streams.

Note any factors that aggravate flood problems:

Although flooding may occur in the study area in any season, the most severe floods are typically associated with intense cloudburst type storms that occur between July and September. This high intensity precipitation on steep mountain slopes and armored desert surfaces produces rapid, high rates of runoff. Runoff is concentrated in the lower valley where the largest population exists. There is a high potential for the public to underestimate the potential for flooding and to be unaware of floods until it is too late to avoid damages or injury. Factors that contribute to these problems include the arid nature of the area, rapid rates of runoff, localized nature of cloudburst precipitation that can result in flooding many miles away from the center of the cloudburst, and the popularity of the area with tourists.

Provide photos of flooding, flood control structures, etc. (with location of photo noted):

Principal flood control facilities in the study area include the King Charles Channel (Photo 1); "N" Channel Diversion (Photo 2); North Las Vegas Detention Basin (Photo 3); North Las Vegas Detention Basin Diversion Dike (Photo 4); Upper Las Vegas Wash Detention Basin (Photo 5); and Upper Las Vegas Wash Interception Berm (Photo 6). The West Range Wash Diversion Dike (Photo 7) is not included in the study area, but diverts flow from the West Range Wash into the North Las Vegas Detention Basin.

2.4 Flood Protection Measures

Describe all flood protection structures and floodplain management measures used to reduce potential flood damage:

The Clark County Regional Flood Control District first adopted a Flood Control Master Plan in 1986. Periodic Master Plan Updates are used to account for changes in land use, construction of new facilities, and improved data. Master planned facilities constructed in the study area include the Upper Las Vegas Wash Detention Basin and Interception Berm (1992); North Las Vegas Detention Basin and Diversion Dike (1984); King Charles Channel (Phase 1 1987; Phase 2 1990); "N" Channel Diversion (Phase 1 1987; Phase 2 1990); and the Upper Las Vegas Wash channel constructed as part of improvement plans for 142 acres between Lone Mountain Road and Craig Road (1997).

The Upper Las Vegas Wash Interception Berm is designed to intercept flows at the upper end of the study area and divert them into the Upper Las Vegas Wash Detention Basin. This basin has a low level outlet as well as a roller compacted concrete spillway. Outflows from the upper basin are confined in an incised wash channel. A diversion dike intercepts flows in this incised channel and diverts them to the North Las Vegas Detention Basin. The West Range Wash Diversion Dike runs across the face of a large alluvial fan to the east of this basin, and also diverts flows into the basin. The North Las Vegas Detention Basin has both low level and spillway outlets that discharge into the wash channel. Flows are conveyed in the natural wash channel until reaching Lone Mountain Road, where they are intercepted by a constructed channel approach to the bridge at Lone Mountain Road. A constructed channel with earth bottom (with gabion grade controls) and riprapped banks carries flows to the Craig Road bridge, where flows enter the concrete lined King Charles Channel. Flows are carried in this lined channel under the Union Pacific Railroad bridge. Downstream of the bridge, a portion of the flows are diverted into the concrete lined "N" Channel Diversion to a culvert crossing of I-15. The flows remaining in the main channel (King Charles Channel) are conveyed in a concrete lined channel parallel to the Interstate to the confluence of the channel with the "A" Channel. The Western Tributary Channel also enters this confluence from the west.

Mention all dams, including those affecting the communities that lie outside the community:

Dams in the study area include those listed above for the North Las Vegas Detention Basin and the Upper Las Vegas Detention Basin.

Mention dams within the community used for purposes other than flood control:

None.

If levees are mentioned, state whether the levees meet or fail to meet the FEMA 3-foot freeboard requirement.

The berm along the south side of the Upper Las Vegas Wash Interception Berm meets the FEMA freeboard requirements. The Diversion Dike at the upper end of the North Las Vegas Detention Basin would not meet this criterion. However, for the purpose of this study case, it has been assumed to remain in place during a 100-year event.

3.0 ENGINEERING METHODS *(Note any digital methodologies used)*

3.1 Hydrologic Analyses

Describe the hydrologic analyses for all flooding sources studied in detail:

Previous hydrologic analyses conducted by the US Army Corps of Engineers (1988), James M. Montgomery (1991), Boyle Engineering Corporation (1991), and Black & Veatch (1993) were reviewed during the study (References 7,8,9,10). The previous studies considered numerous separate storm centerings to identify the storm configurations that produced the highest peak flows at various locations in the basin. These studies utilized HEC-1 models (Reference 11) to estimate peak flows for various recurrence intervals. These models were calibrated to the Corps of Engineers regional analysis curve. The conclusions of the previous studies with respect to critical storm centerings were reviewed and accepted for this study:

- the "Spring Mountain Storm" produces the highest uncontrolled peak inflows to the Upper Las Vegas Wash Interception Berm and Detention Basin;
- the "Interbasin Storm" produces the highest 100-year peak inflow to the North Las Vegas Wash Detention Basin; and
- an unnamed storm in the West Range Wash tributary area produces the highest peak inflows to the West Range Wash Diversion Dike (although the West Range Wash Diversion Dike is not a part of the study area, flows were modeled for the purpose of reviewing the potential impact of the structure's performance on flows in Las Vegas Wash downstream, and for determining flood elevations in the North Las Vegas Detention Basin).

The previously developed HEC-1 models were modified to reflect the presence and current outlet work configurations of the existing flood control facilities. In addition, the models were expanded to represent 10- and 50- year rainfall events for the Interbasin Storm, and 500-year events for the Spring Mountain, Interbasin, and West Range Wash storms.

No changes were made to the previously defined runoff and channel routing parameters (including basin areas, curve numbers, loss rates, channel geometry, channel routing parameters, or rainfall amounts). Review of the existing models indicated that these values were all consistent with the Clark County Regional Flood Control District Hydrologic Criteria and Drainage Design Manual (Reference 12).

Changes were made in the existing HEC-1 models to reflect as-built stage -storage and stage-discharge relationships for the Upper Las Vegas Wash Detention Basin (Reference 9), and to reflect the stage-discharge relationship for the modified three-pipe outlet structure at the North Las Vegas Detention Basin, including the upstream barrier wall.

Rainfall amounts for the 500-year Spring Mountain Storm, not previously modeled, were determined by extrapolation of the 10-, 50-, and 100-year rainfall amounts in previous models (Reference 7). Rainfall amounts for the 10- and 50-year Interbasin Storm events, not previously modeled, are based on the precipitation amounts for the Lower Central Valley storm (Reference 7) and the NOAA Atlas 2 (Reference 13) for Nevada, adjusted to reflect appropriate depth-area reduction factors from the Hydrologic Criteria and Drainage Design Manual. Rainfall amounts for the 500-year Interbasin Storm event were determined by extrapolation of the 10-, 50-, and 100-year rainfall amounts. Rainfall amounts for the 500-year West Range Wash storm event were determined by extrapolating rainfall amounts from the previous models for the 10-, 50-, and 100-year events.

The analyses produce results similar to the previously adopted FIS discharges for the 10- through 100-year peak discharges. The revised hydrologic analyses produce an increase of approximately 80% over the previously adopted FIS peak discharge for the 500-year event. This change is due to a loss of flow control at the detention basin that was not addressed in previous models.

Peak discharges determined using HEC-1 were applied in the computation of water surface profiles for the portion of the study area upstream of the outflow from the North Las Vegas Detention Basin. Downstream of this point, the 500-year peak discharge exceeded channel capacity, and flows were lost from the main channel at several points. Peak discharges were computed in this area using the HEC-1 results for the computation node downstream of the North Las Vegas

Detention Basin at the upstream end of this reach, and the results of the hydraulic analyses described in Section 3.2 to determine flow splits and losses from the main channel. Where significant flows were lost from the main channel, they were subtracted from the total flow downstream. Where flows were determined to re-enter the channel, they were added to the remaining flows in the main channel.

In a summary of discharges table, provide a summary of drainage area-peak discharge relationships for the streams studied by detailed methods. Discharges and drainage areas for each stream should be listed in descending order. Streams should be listed in the same order as flood profiles:

Summary of Peak Discharges (in cfs) for Las Vegas Wash

Location	Storm Area, sq.mi. [a]	Storm Return Period 10-year	50-year	100-year	500-year
King Charles Channel below N Channel Diversion	54.4 [b]	1,025	1,746	2,266	4694 [d]
N Channel					
I-15 to Donovan Road	NA	256	436	567	2025 [d]
Donovan Road to King Charles		256	436	567	1173 [d]
Downstream of North Las Vegas Detention Basin	54.4 [b]	1,281	2,183	2,833	8,988
North Las Vegas Detention Basin Pipe and Spillway	54.4 [b]	1,292	2,186	2,839	6,322
Diversion Dike Overflow at North Las Vegas Detention Basin	54.4 [b]	0	0	194	6,838
Inflow to North Las Vegas Detention Basin	54.4 [b]	2,939	6,751	8,343	11,017
Inflow to North Las Vegas Detention Basin Diversion Dike	54.4 [b]	2,939	6,751	8,537	17,855
Outflow from Upper Las Vegas Wash Detention Basin	136.3 [c]	2,426	3,888	5,019	19,217
Inflow to Upper Las Vegas Wash Detention Basin	136.3 [c]	3,465	10,312	14,737	24,938

a Storm area is smaller than total tributary area
b Reference 10
c Reference 8
d Discharges based on upstream flow splits from hydraulic analysis

If applicable, discuss methods used to determine stillwater elevations and reference the Summary of Stillwater Elevations table:

Not applicable.

3.2 Hydraulic Analyses

State how cross sections were developed for all streams studied by detailed methods:

Cross sections were developed from four primary sources:

- aerial photogrammetry;
- field surveys;
- as-built plans for flood control facilities; and
- improvement plans for streets, bridges and development areas.

Aerial photogrammetry was used to develop topographic maps of the study area with a contour interval of 4 feet (Reference 13). Cross sections were developed by photogrammetric methods for most of the upper portion of the study area where there are few flood control channel improvements. Additional cross sections were developed directly from the aerial topographic mapping where determined necessary based on preliminary hydraulic analyses. Additional field surveys were conducted to obtain elevations for the bridge crossings of Upper Las Vegas Wash at Lone Mountain Road, Craig Road, and the Union Pacific Railroad Bridge. Field surveys were also conducted to increase the density of topographic data near the intersection of Losee Road and Lone Mountain Road, where flows from the wash cross Losee Road in two low water crossings. As-built plans for the King Charles Channel (References 14, 15), Improvements for 142 acres at Losee Road and Craig Road (Reference 16), Lone Mountain Road Bridge (Reference 17), North Las Vegas Detention Basin (Reference 18), Upper Las Vegas Wash Detention Basin and Interception Berm/Channel (Reference 19) were used to develop cross sections in these areas.

The following table describes the cross section data used:

Cross Section Station	**Data Source**
1+50 to 37+20	As-built plans - King Charles Diversion Channel Phase 1
37+20 to 58+53	As-built plans - King Charles Diversion Channel Phase 2; field survey at UPRR bridge

58+53 to 86+82	As-built improvement plans - 142 acre development at Losee Road and Craig Road; field survey at Craig Road bridge
87+80 to 88+61	As-built plans - Lone Mountain Road Bridge; field survey at Lone Mountain Road bridge; As-built improvement plans - 142 acre development and Losee Road and Craig Road
91+20	Aerial photogrammetry
92+37 to 94+29	Aerial topographic mapping
101+55 to 141+67	Aerial photogrammetry
143+68	Aerial topographic mapping
151+14	Aerial photogrammetry
156+67	Aerial topographic mapping
165+46 to 184+36	Aerial photogrammetry
184+62 to 192+15	Aerial topographic mapping
198+02 to 263+83	Aerial photogrammetry
270+00 to 273+03	Aerial topographic mapping
289+03 to 309+35	As-built plans - Las Vegas Detention Basin Flood Control Project
312+35 to 315+00	Aerial topographic mapping
320+44 to 555+70	Aerial photogrammetry
560+10 to 564+87	As-built plans - Upper Las Vegas Detention Basin and Interception Berm/Channel

59+059 to 749+97 Aerial photogrammetry

Describe how the dimensions of hydraulic structures were determined:

The dimensions of major hydraulic structures, including the outlet dams and outlet works for the two detention basins and their interception and diversion channels, were determined from as-built drawings. Field surveys were completed at all bridge crossings.

Explain how channel roughness factors (Manning's "n") were assigned. The "n" values for ALL streams studied by detailed methods (channel and overbank areas) should be given:

Channel roughness factors were determined based on standard hydraulic engineering references (References 20, 21), engineering judgment, and field observations. Limited sensitivity testing was conducted during hydraulic modeling to determine the effect of a range of 'n' values on model results. Final model roughness values were selected to represent a combination of roughness due to vegetation, bed and bank material, and bed form irregularity. The depth of flow was also considered in selecting appropriate 'n' values. The following Manning's 'n' values were assigned to various channel and overbank areas:

Channel/Overbank Type	**Manning's 'n'**
Concrete lined channel	0.014 to 0.017
Developed overbanks (Primarily pavement areas, smooth earth, or sparse landscaping)	0.030 to 0.035
Earth channels (constructed)	0.030
Unimproved wash channels (with vegetation)	0.040 to 0.045
Industrial lots (with obstructions)	0.045

State how water surface elevations were obtained for all streams studied by detailed methods:

The US Army Corps of Engineers HEC-2 program (Reference 22) was used as the primary tool for computation of water surface profiles for this study. This model was run in both subcritical and supercritical modes for various reaches of the study area. The results of the HEC-2 model were supplemented by independent calculations at bridges and culverts using the Federal Highway Administration HY-8 program (Reference 23) and by hand. Shallow overbank flooding depths and velocities were computed in some areas by hand using normal depth computations from Manning's equation.

Flood profiles were drawn showing computed water surface elevations for floods of the selected recurrence intervals. Peak discharges on the "A" Channel were found to produce backwater in the lower portion of the King Charles Channel with higher water surface elevations than HEC-2 models for the corresponding recurrence intervals on the King Charles Channel. The water surfaces from backwater on the "A" Channel are shown in the profiles. Maximum basin stages in the North Las Vegas Detention Basin and Upper Las Vegas Detention Basin computed using the HEC-1 models, produced higher water surface elevations for the 50-, 100-, and 500-year flood events than the HEC-2 models for the portions of the wash immediately upstream of the basins. These elevations are reflected on the profiles.

The starting water surface elevations for the Upper Las Vegas Wash at the confluence with the "A" Channel were calculated using the slope area method. Water surface elevations at the N Channel were computed using supercritical profiles. These starting water surfaces match the water surface elevations calculated at the diversion from the King Charles Channel. Starting water surface elevations at the North Las Vegas Detention Basin were derived from HEC-1 routing of flows through the basin. The starting water surface elevations were taken as the basin stage at the time of the peak discharge. The starting water surface elevations in Upper Las Vegas Detention Basin were computed using the same methods.

The hydraulic analyses for this study were based on unobstructed flow through the wash and hydraulic structures except at Lone Mountain Road Bridge. Lone Mountain Road Bridge is the first bridge that Upper Las Vegas wash passes through moving downstream and is subject to high debris and sediment loads from the wash. The bridge is subject to pressure flow at the 500-year peak discharge. Under these conditions, the capacity of the bridge to transport large bed load sediments will be less than the capacity of the inflowing channel. Due to the high availability of cobble sized bed load that can be generated by progression of existing headcuts upstream of the bridge, opening was assumed blocked during the 500-year peak discharge.

The HEC-2 models and the HY-8 program were used to define the locations where channel and hydraulic structure capacities were inadequate to convey the peak flood discharges for various recurrence intervals. Where overbank flows remained hydraulically connected to the main wash or channel flows, the overbank flows were modeled with HEC-2, and the results used to delineate AE flood hazard zones. Where breakout flows were determined likely to become hydraulically separated from the main wash or channel, the breakout flow depths and velocities were estimated using normal depth computations, and the results of these computations used to delineate AO flood hazard zones. Breakout flows occur at

the 500-year flood discharge near Azure and Losee Road, Lone Mountain Road, Craig Road, and the UPRR Bridge. A portion of these flows return to the main channel downstream in various locations within the study area. Overflow magnitudes were determined using HEC-2 and hand calculations. For determination of the profiles in the main channel or wash downstream of breakout flows, the overflow was subtracted from the total flow upstream. Flows in the HEC-2 models decrease in a downstream direction as overflows are progressively subtracted from the main flow area at subsequent breakout locations.

Average 100-year flow depths in overflow areas were determined using normal-depth calculations. Areas of inundation for the 500-year flood discharge were determined by approximate methods using a combination of normal depth calculations, review of available topographic mapping, and field observation.

Shallow flooding is often characterized by highly unpredictable flow directions caused by low relief or shifting channels and high debris loads. Where such conditions exist, the entire area susceptible to this unpredictable flow was delineated as a zone of equal risk. Small scale topographic variations were averaged across inundated areas to determine flood depths.

Describe the methodology for wave height/runup, lacustrine, ice jam, alluvial fan flooding, and shallow flooding areas (where applicable):

Not applicable.

If applicable, reference the Transect Descriptions which should include: transect number, location, 100-year stillwater elevation, and maximum 100-year wave elevation.

Not applicable.

If performed, describe the hydraulic analyses for the approximate flooding sources:

No approximate flooding sources studied.

If applicable, reference the Transect Data Table which should include: Flooding Source (with the affected transects), 10-, 50-, 100-, and 500-year stillwater elevation, zone designation and Base Flood Elevation.

Not applicable.

If applicable, reference the Transect Location Map.

Not applicable.

Standard paragraphs in this section include paragraphs for cross sections, NGVD, and unobstructed flow.

No modifications required to standard paragraphs, except that the Lone Mountain Road Bridge was assumed blocked in the 500-year event as described above.

Specify whether elevations are referenced to NGVD or NAVD or other datum, and give releveling dates, if any.

All elevations are referenced to NGVD (1929).

4.0 FLOODPLAIN MANAGEMENT APPLICATIONS

4.1 Floodplain Boundaries

Identify all maps used. Include the scale, contour interval, and type of map (topographic, compiled from aerial photographs, etc):

Flood boundaries for the 100- and 500-year flood discharges in the Upper Las Vegas Wash were delineated on 1:4,800 scale topographic maps with a contour interval of 4 feet (reference 24). Where flood boundaries for the 500-year flood discharge was located outside the extent of this mapping, the boundaries were determined using topographic mapping developed for the City of North Las Vegas at a scale of 1:4,800 with a contour interval of 2 feet (reference 25) and USGS quadrangle topographic maps, 1:24,000 (references 26 and 27).

Cross sections within the unimproved areas of the wash were obtained by aerial photogrammetry and interpolated from topographic maps. Cross sections at structures were obtained from as-built plans and verified by field inspections and surveys.

There is a datum difference between the NGVD 1929 and NAVD 1988 mapping from ranging 2.41 to 2.46 feet in the Upper Las Vegas Wash. The average difference between the control points was 2.43 feet. Therefore, 2.43 feet was subtracted from the photogrammetric control and the ERM elevations to convert from NAVD 1988 to NGVD 1929. Cross section elevations obtained from NAVD 1988 topographic mapping used in the hydraulic models were converted to NGVD 1929 by subtracting 2.4 feet.

Identify and reference all maps or methods used to delineate floodplain boundaries for approximate flooding sources:

Not applicable.

4.2 Floodways

List streams, if any, for which floodway widths extend beyond the corporate limits:

No floodway determined.

List streams affected by backwater:

The lower portion of the King Charles Channel is affected by backwater from the "A" Channel. These two channels have there confluence at the study area downstream boundary near Interstate 15. The "A" Channel backwater elevations were extended upstream to intersect with the computed water surface elevations in the King Charles Channel.

Provide method used for floodway computations:

No floodway determined.

Give reason why no floodway was delineated for streams or portions of streams:

Determination of a floodway was discussed, but not requested by community at the initial CCO meeting, due to anticipated confinement of 100-year flood in natural and constructed channel boundaries. The FEMA Project Officer agreed that a floodway was not required.

Identify any abnormal procedures (such as state-imposed surcharges of less than 1.0 foot) for floodway delineations:

No abnormal procedures.

7.0 OTHER STUDIES

Identify and reference all other FISs for contiguous communities and any other published reports or available data dealing with related flooding sources. All disagreements and discrepancies must be noted and resolved:

This report is for a restudy of one of the streams covered in the current Flood Insurance Study for Clark County, Nevada and Incorporated Areas (Reference 4). Changes in discharges and water surface profiles in this study are due to the recent construction of flood control facilities.

Introduction to Volume 6

This volume of the TSDN contains study report data and flood profiles. The study was completed for two cases due to uncertainty regarding the performance of the North Las Vegas Detention Basin Diversion Dike during a major flood event. This volume contains the report data and profiles for the '**Without North Las Vegas Detention Basin Diversion Dike**' case. Volume 5 contains similar data for the "With North Las Vegas Detention Basin Diversion Dike'. A discussion of the evaluation of the diversion dike and other flood control structures in the study area is included in Volume 2.

Flood Insurance Study

Clark County, Nevada

Without NLVDB Diversion Dike

1.0 INTRODUCTION

1.1 Purpose of Study

Community Name: City of North Las Vegas; City of Las Vegas; Unincorporated Areas of Clark County
County: Clark County
State: Nevada

1.2 Authority and Acknowledgments

Study Contractor: Northwest Hydraulic Consultants, Inc.
*Subcontracto*r: Kenney Aerial Mapping (Mapping and Surveying)
Completion Date: April, 1998

Provider of Base Map: Kenney Aerial Mapping, Inc.

Base Map Compilation Source: Kenney Aerial Mapping, Inc
Base Map Compilation Scale: 1:4800
Base Map Compilation Date: August, 1996

Coordinate System: State Plane
Projection: State Plane
Datum: NGVD 1929

Has base map source been modified?

Yes

If so, how and where:

Corporate limits, section lines, and streets were added based on information provided by the City of Las Vegas and the City of North Las Vegas from community GIS mapping.

Any restrictions on the release of base map data?

No

If yes, what restrictions apply?

1.3 Coordination

Initial Consultation and Coordination Officer's (CCO) meeting date:

Wednesday, September 7, 1994

List of attendees and agencies represented at the initial CCO meeting:

Leslie K. Sakumoto, P.E. - FEMA Project Officer
Randy Tarr - City of North Las Vegas
Kevin Eubanks - Clark County Regional Flood Control District
Tom Chiatovich - City of Las Vegas
Bob Murnane - City of North Las Vegas
Phu Simpson - Clark County
Bob MacArthur, Northwest Hydraulic Consultants
Ed Wallace, Northwest Hydraulic Consultants

Intermediate CCO meeting data and attendees (if applicable):

Not applicable.

List of contacts made for the purpose of acquiring information:

Flooding sources requiring detailed study were discussed at the initial community meeting on September 7, 1994 involving representatives from FEMA, Clark County Regional Flood Control District, Clark County, City of North Las Vegas, and City of Las Vegas. Additional contacts were made with each of these agencies during the course of the study to obtain information. Additional contacts for the purpose of obtaining information were made with the US Geological Survey, Desert Research Institute, and FEMA's LMMP contractor, Ensign & Buckley Consulting Engineers.

The study contract was executed on September 25, 1995, and the first site visit and informational meetings were held on September 27 and 28, 1995. Separate meetings were held with the flood control district and each of the three communities in the study area to research available hydrologic and hydraulic

reports, design documents for flood control facilities, as-built plans for bridges and other infrastructure, and available topographic mapping and aerial photography. A second site visit for the purpose of geomorphic reconnaissance was conducted on December 6 and 7, 1995. A meeting was held with Clark County Regional Flood Control District at this time to discuss available information for the West Range Wash Diversion Dike, North Las Vegas Detention Basin and Diversion Dike, and Upper Las Vegas Detention Basin and Interception Berm; key hydrologic studies and precipitation analysis by the Corps of Engineers and NOAA; and existing sedimentation analyses for the diversion facilities.

The review of information provided by FEMA and the communities revealed gaps in the information regarding the design of the flood control facilities in the project area, including the two detention basins and three diversion dikes in the upper portion of the study area. A second site visit and meetings with Clark County Regional Flood Control District and the City of North Las Vegas were conducted on April 17 and 18, 1996. Additional information was obtained at these meetings, including review of microfiche files for the King Charles Channel, N Channel, and two bridges across Upper Las Vegas Wash. Blueline plans for these facilities were provided by the City of North Las Vegas on May 29, 1996.

Following the site review and initial hydraulic analysis, the study contractor requested additional information from the City of North Las Vegas regarding the status of the Sunrise Memorial Park development project and the control of debris in the Upper Las Vegas Wash channel. The City of North Las Vegas provided additional information in a letter dated June 21, 1996, advising the study contractor to consider the planned channel improvements at Sunrise Memorial Park in the hydraulic analysis, and that debris in the Upper Las Vegas Wash is scheduled for annual cleanup.

On August 13, 1996 the study contractor conducted a meeting with FEMA's project officer to discuss the results of preliminary hydrologic and hydraulic analysis. At this meeting, concerns were raised regarding the adequacy of available information in assessing the performance of the three diversion structures in the upper portion of the study area. The study contractor submitted preliminary hydrology and hydraulic information to FEMA on August 29, 1996 relating to these structures. In a September 12 conference call with representatives of FEMA, the study contractor was directed to assume that the Upper Las Vegas Wash Interception Berm would perform adequately in containing the base flood. It was agreed in this meeting that adequate information was not available to assess the performance of the West Range Wash Diversion Dike or the North Las Vegas Detention Basin Diversion Dike.

FEMA requested additional information from the Clark County Regional Flood Control District in a letter dated September 5, 1996, and subsequently notified the District on November 17, 1996 that work on the study had been suspended pending review of additional information on the West Range Wash Diversion Dike. FEMA's Technical Evaluation Contractor (TEC) also began research into review documentation for the North Las Vegas Detention Basin Diversion Dike. FEMA issued a Letter of Map Revision for the West Range Wash Diversion Dike on January 28, 1997, but FEMA's research (concluded in April 1997) failed to reveal adequate information regarding performance of the North Las Vegas Diversion Dike if subjected to current estimates of the 100-year discharge.

The study contractor summarized the changes in estimated 100-year discharges and concerns regarding performance of the North Las Vegas Diversion Dike in an April 28, 1997 letter to FEMA, and FEMA advised the Clark County Regional Flood Control District of the situation in a May 5, 1997 letter. The Clark County Regional Flood Control District advised FEMA in a June 26, 1997 letter that the District agreed that the impacts of sediment on the structure, and the stability of the structure if overtopped, warranted further consideration. The District undertook an independent evaluation of the diversion dike, and provided a report summarizing the results dated February 25, 1998.

To avoid delay in the completion of the study, the study contractor was directed by FEMA to complete hydraulic analysis of independent study cases with and without the North Las Vegas Detention Basin Diversion Dike.

The study contractor conducted a meeting with FEMA on December 11, 1997 and received information regarding a November 20 , 1997 LOMR issued in the study area between Lone Mountain Road and Craig Road. The study contractor conducted a site visit on December 13, 1997 to verify the conditions in the area of the LOMR and the remainder of the study area.

The study contractor met with the FEMA project officer on March 19,1998 to review the results of revised hydraulic analysis including the two cases with and without the North Las Vegas Detention Basin Diversion Dike, and the changes associated with the LOMR.

2.0 AREA STUDIED

2.1 Scope of Study

Note areas excluded from study, as well as areas of extraterritorial jurisdiction:

The study area includes the areas potentially subject to flooding from Upper Las Vegas Wash upstream of Interstate 15, including portions of the City of North Las Vegas, the City of Las Vegas, and unincorporated areas of Clark County. The study area's upstream (northwest) end is the upper end of the Upper Las Vegas Wash Interception Berm in Section 4, Range 60 East, Township 19 South in the City of Las Vegas. It extends from this point eastward to the North Las Vegas Detention Basin in the City of North Las Vegas in Section 14, Range 61 East, Township 19 South, thence southward through portions of Clark County and the City of North Las Vegas to Interstate 15 near Gowan Road in Section 11, Range 61 East, Township 20 South. The study area excludes the areas southeast of Interstate 15; northwest of the North Las Vegas Detention Basin along the West Range Wash Diversion Channel; and north of the Upper Las Vegas Wash and Upper Las Vegas Wash Interception Berm channels.

List the flooding sources studied in detail (detailed study streams should be listed in the same order as they appear in profiles). If they are also partially studied by approximate methods, provide the limits of detailed study:

The flooding source studied in detail is the portion of Las Vegas Wash generally known as Upper Las Vegas Wash, located northwest of Interstate 15, including the following channel segments as referred to in the Clark County Regional Flood Control District August 1991 Master Plan Update of the Las Vegas Valley (Reference 1):

Upper Las Vegas Wash - King Charles Channel
Upper Las Vegas Wash
"N" Channel Diversion

List the flooding sources studied by approximate methods:

None

If applicable, discuss streams on which study was terminated where the 100-year floodplain permanently narrowed to less than 200 feet wide or for which detailed study was ended where the drainage area was less than 1 square mile:

None

2.2 Community Description

Provide a general description of the community's location within the county and state:

Clark County is located in the southern tip of Nevada. The greater Las Vegas metropolitan area, including the City of Las Vegas, City of North Las Vegas, and development within the unincorporated areas of Clark County, is located in the central part of Clark County, approximately 20 miles west of Lake Mead. The study area is located in the northern portion of the Las Vegas metropolitan area.

List surrounding communities and their locations with respect to the subject community:

Surrounding communities include the town of East Las Vegas, approximately 10 miles southeast; the City of Henderson, approximately 15 miles southeast; and Boulder City, approximately 25 miles southeast.

List other nearby large cities and their locations:

Las Vegas is located approximately 250 miles northeast of Los Angeles, California; 360 miles southwest of Salt Lake City, Utah; and 340 miles southeast of Reno, Nevada.

Briefly describe the community. This description may include patterns of residential and commercial development; the extent and nature of floodplain development; natural features that affect flood hazards in the community; and sufficient description of climatic, physiographic, and land use features to support the discussion of flood problems that follows (Section 2.3).

The topographic features of Clark County are generally typical of the Basin and Range physiographic province, with north-south trending ranges. Las Vegas Valley cuts diagonally across the county, following a line of geologic deformation indicated by bending of the north-south trending ranges. Major ranges in the area include the Spring Mountain Range to the west, and the Sheep Mountain Range and Las Vegas Range to the north. The elevations of Las Vegas Valley are between approximately 3000 feet and 1800 feet (National Geodetic Vertical Datum, NGVD), and elevations of peaks in the surrounding ranges reach up to nearly 12,000 feet in the Spring Mountain Range and 10,000 feet in the Sheep Mountain Range. A series of large, coalescing alluvial fans are located along the margins of the upper portion of the valley at the base of the ranges. Much of the upper Las Vegas Valley floor is comprised of fine-grained lacustrine sediments.

Marginal areas of the upper valley, and the lower Las Vegas Valley are covered by alluvial deposits. (References 2, 3).

The climate is arid to semi-arid, characterized by infrequent rainfall, low humidity, and wide extremes in daily temperatures. Annual precipitation in the area is strongly correlated to elevation, but intense cloudburst storms are possible in all areas of the Las Vegas Valley and surrounding ranges. The Las Vegas Valley receives an average annual rainfall of approximately 4 inches, and the higher elevations in the county receive up to 20 inches. Precipitation varies greatly in any location from year to year due to local cloudburst events. The average annual temperature is approximately 66^0 F, with average daily maximums in the high 70's and average daily minimums in the mid 50's. Daily maximum temperatures usually exceed 100^0 F in the summer in the lower valley, and daily minimum temperatures drop below 20^0 F in the mountain ranges in the winter.

Vegetation is strongly zoned by elevation, with little or no vegetation on the playas, and sparse vegetation in the lower valleys. Species in the lower valleys are generally phreatophytes. Creosote bush, saltbrush, and rabbitbrush are common on the alluvial slopes, and Joshua trees, Spanish bayonet, small cacti, and blackrush grow on the middle portions of the fans. Above approximately 4,500 feet there are wooded areas of pinion and juniper (Reference 3).

The developed area of Clark County is concentrated in the Las Vegas Valley. Growth has been extremely rapid over the past 60 to 70 years, increasing from less than 5,000 in 1920 to approximately 600,000 in 1986. The current population is approximately 1.1 million. A large portion of the population is located in unincorporated areas of Las Vegas Valley. The developed area is located primarily in the lower portions of Las Vegas Valley, and is subject to runoff concentrated in the lower valley from a large surrounding geographic area. Development in the study area along Upper Las Vegas Wash, King Charles Channel, and "N" Channel includes low density residential, commercial, and industrial development. Extensive additional development, especially commercial and industrial development in North Las Vegas, is planned in the near future. This development is planned within the area formerly mapped within the 100-year flood hazard zone by FEMA in 1995 (Reference 4).

In addition to the permanent population, a large visitor population is present in the Las Vegas Valley throughout the year. The visitor population is generated primarily by the gaming and entertainment industries, which are a prime element in the County's economy.

2.3 Principal Flood Problems

Include the discharges and recurrence intervals of major floods:

Reports of flooding in the Las Vegas area date back almost 100 years. The U.S. Soil Conservation Service reviewed historical flooding in a report entitled History of Flooding, Clark County, Nevada 1905-1975 (Reference 5). This report documented 184 flood events that resulted in damages to private property and public facilities. Since 1960, the Las Vegas area has experienced at least seven floods that caused damages in excess of one million dollars, and the loss of over 22 lives in nine separate flash flood events (Reference 6).

The largest recorded flood on Las Vegas Wash occurred on July 3, 1976, when 12,000 cfs was measured at the USGS gaging station located upstream of Las Vegas Boulevard north of Las Vegas. The next largest events occurred on May 31, 1973 (1,640 cfs) , and September 25, 1967 (1,170 cfs). Although recurrence intervals for these events have previously been estimated by others (Reference 4), the construction of flood control facilities in the upper portion of the study area have altered flood flow paths and added flood storage to the extent that these estimates have little bearing on current recurrence intervals and flood discharges.

Give the location (city and state) of all stream gages for studied streams:

USGS Gages 09419648 (Las Vegas Wash above Detention Basin near North Las Vegas) and 09419650 (Las Vegas Wash at North Las Vegas) were discontinued in 1993 an 1978, respectively. There are no known active gaging stations on the studied streams.

Note any factors that aggravate flood problems:

Although flooding may occur in the study area in any season, the most severe floods are typically associated with intense cloudburst type storms that occur between July and September. This high intensity precipitation on steep mountain slopes and armored desert surfaces produces rapid, high rates of runoff. Runoff is concentrated in the lower valley where the largest population exists. There is a high potential for the public to underestimate the potential for flooding and to be unaware of floods until it is too late to avoid damages or injury. Factors that contribute to these problems include the arid nature of the area, rapid rates of runoff, localized nature of cloudburst precipitation that can result in flooding many miles away from the center of the cloudburst, and the popularity of the area with tourists.

Provide photos of flooding, flood control structures, etc. (with location of photo noted):

Principal flood control facilities in the study area include the King Charles Channel (Photo 1); "N" Channel Diversion (Photo 2); North Las Vegas Detention Basin (Photo 3); North Las Vegas Detention Basin Diversion Dike (Photo 4); Upper Las Vegas Wash Detention Basin (Photo 5); and Upper Las Vegas Wash Interception Berm (Photo 6). The West Range Wash Diversion Dike (Photo 7) is not included in the study area, but diverts flow from the West Range Wash into the North Las Vegas Detention Basin.

2.4 Flood Protection Measures

Describe all flood protection structures and floodplain management measures used to reduce potential flood damage:

The Clark County Regional Flood Control District first adopted a Flood Control Master Plan in 1986. Periodic Master Plan Updates are used to account for changes in land use, construction of new facilities, and improved data. Master planned facilities constructed in the study area include the Upper Las Vegas Wash Detention Basin and Interception Berm (1992); North Las Vegas Detention Basin and Diversion Dike (1984); King Charles Channel (Phase 1 1987; Phase 2 1990); "N" Channel Diversion (Phase 1 1987; Phase 2 1990); and the Upper Las Vegas Wash channel constructed as part of improvement plans for 142 acres between Lone Mountain Road and Craig Road (1997).

The Upper Las Vegas Wash Interception Berm is designed to intercept flows at the upper end of the study area and divert them into the Upper Las Vegas Wash Detention Basin. This basin has a low level outlet as well as a roller compacted concrete spillway. Outflows from the upper basin are confined in an incised wash channel. A diversion dike intercepts flows in this incised channel and diverts them to the North Las Vegas Detention Basin. The West Range Wash Diversion Dike runs across the face of a large alluvial fan to the east of this basin, and also diverts flows into the basin. The North Las Vegas Detention Basin has both low level and spillway outlets that discharge into the wash channel. Flows are conveyed in the natural wash channel until reaching Lone Mountain Road, where they are intercepted by a constructed channel approach to the bridge at Lone Mountain Road. A constructed channel with earth bottom (with gabion grade controls) and riprapped banks carries flows to the Craig Road bridge, where flows enter the concrete lined King Charles Channel. Flows are carried in this lined channel under the Union Pacific Railroad bridge. Downstream of the bridge, a portion of the flows are diverted into the concrete lined "N" Channel Diversion to a culvert crossing of I-15. The flows remaining in the main channel (King Charles

Channel) are conveyed in a concrete lined channel parallel to the Interstate to the confluence of the channel with the "A" Channel. The Western Tributary Channel also enters this confluence from the west.

Mention all dams, including those affecting the communities that lie outside the community:

Dams in the study area include those listed above for the North Las Vegas Detention Basin and the Upper Las Vegas Detention Basin.

Mention dams within the community used for purposes other than flood control:

None.

If levees are mentioned, state whether the levees meet or fail to meet the FEMA 3-foot freeboard requirement.

The berm along the south side of the Upper Las Vegas Wash Interception Berm meets the FEMA freeboard requirements. The Diversion Dike at the upper end of the North Las Vegas Detention Basin would not meet this criterion. In this study case, it has therefore been assumed that the dike is not in place at the peak discharge of a 100-year event.

3.0 ENGINEERING METHODS *(Note any digital methodologies used)*

3.1 Hydrologic Analyses

Describe the hydrologic analyses for all flooding sources studied in detail:

Previous hydrologic analyses conducted by the US Army Corps of Engineers (1988), James M. Montgomery (1991), Boyle Engineering Corporation (1991), and Black & Veatch (1993) were reviewed during the study (References 7,8,9,10). The previous studies considered numerous separate storm centerings to identify the storm configurations that produced the highest peak flows at various locations in the basin. These studies utilized HEC-1 models (Reference 11) to estimate peak flows for various recurrence intervals. These models were calibrated to the Corps of Engineers regional analysis curve. The conclusions of the previous studies with respect to critical storm centerings were reviewed and accepted for this study:

- the "Spring Mountain Storm" produces the highest uncontrolled peak inflows to the Upper Las Vegas Wash Interception Berm and Detention Basin;

- the "Interbasin Storm" produces the highest 100-year peak inflow to the North Las Vegas Wash Detention Basin; and

- an unnamed storm in the West Range Wash tributary area produces the highest peak inflows to the West Range Wash Diversion Dike (although the West Range Wash Diversion Dike is not a part of the study area, flows were modeled for the purpose of reviewing the potential impact of the structure's performance on flows in Las Vegas Wash downstream, and for determining flood elevations in the North Las Vegas Detention Basin).

The previously developed HEC-1 models were modified to reflect the presence and current outlet work configurations of the existing flood control facilities. In addition, the models were expanded to represent 10- and 50- year rainfall events for the Interbasin Storm, and 500-year events for the Spring Mountain, Interbasin, and West Range Wash storms.

No changes were made to the previously defined runoff and channel routing parameters (including basin areas, curve numbers, loss rates, channel geometry, channel routing parameters, or rainfall amounts). Review of the existing models indicated that these values were all consistent with the Clark County Regional Flood Control District Hydrologic Criteria and Drainage Design Manual (Reference 12).

Changes were made in the existing HEC-1 models to reflect as-built stage storage and stage-discharge relationships for the Upper Las Vegas Wash Detention Basin (Reference 9), and to reflect the stage-discharge relationship for the modified three-pipe outlet structure at the North Las Vegas Detention Basin, including the upstream barrier wall.

Rainfall amounts for the 500-year Spring Mountain Storm, not previously modeled, were determined by extrapolation of the 10-, 50-, and 100-year rainfall amounts in previous models (Reference 7). Rainfall amounts for the 10- and 50-year Interbasin Storm events, not previously modeled, are based on the precipitation amounts for the Lower Central Valley storm (Reference 7) and the NOAA Atlas 2 (Reference 13) for Nevada, adjusted to reflect appropriate depth-area reduction factors from the Hydrologic Criteria and Drainage Design Manual. Rainfall amounts for the 500-year Interbasin Storm event were determined by extrapolation of the 10-, 50-, and 100-year rainfall amounts. Rainfall amounts for the 500-year West Range Wash storm event were determined by extrapolating rainfall amounts from the previous models for the 10-, 50-, and 100-year events.

Upstream of the North Las Vegas Detention Basin, the analyses produce results similar to the previously adopted FIS discharges for the 10- through 100-year

peak discharges. The revised hydrologic analyses produce an increase of approximately 80% over the previously adopted FIS peak discharge for the 500-year event. This change is due to a loss of flow control at the detention basins that was not addressed in previous models.

Preliminary hydraulic analysis at the North Las Vegas Detention Basin Diversion Dike indicated that a spill over the dike was likely to occur in the 100-year event. In the absence of conclusive data that this diversion dike would be stable under these conditions, the dike was assumed to not be in place for discharges equal to or greater than the 100-year peak discharge. This results in much higher flows downstream of the North Las Vegas Detention Basin for the 100- and 500- year events compared to previous estimates. Peak discharges for the 10- and 50-year events are based on routing through the North Las Vegas Detention Basin.

Peak discharges determined using HEC-1 were applied in the computation of water surface profiles for the portion of the study area upstream of the North Las Vegas Detention Basin. Downstream of this point, the 100- and 500-year peak discharges exceed channel capacity, and flows were lost from the main channel at several points. Therefore, peak discharges and flow splits in the channel and overbank areas downstream of the North Las Vegas Detention Basin were determined in the hydraulic analyses described in Section 3.2. Where significant flows were lost from the main channel, they were subtracted from the total flow downstream. Where flows were determined to re-enter the channel, they were added to the remaining flows in the main channel.

In a summary of discharges table, provide a summary of drainage area-peak discharge relationships for the streams studied by detailed methods. Discharges and drainage areas for each stream should be listed in descending order. Streams should be listed in the same order as flood profiles:

Summary of Peak Discharges (in cfs) for Las Vegas Wash

Location	Storm Area, sq.mi. [a]	Storm Return Period 10-year	50-year	100-year	500-year
King Charles Channel below N Channel	54.4 [b]	1,025	1,746	4,623 [d]	5,833 [d]
N Channel					
I-15 to Donovan Road	NA	258	437	1,975 [d]	2,526 [d]
Donovan Road to King Charles	NA	258	437	1,156 [d]	1,248 [d]
Downstream of North Las Vegas Detention Basin	54.4 [b]	1,281	2,183	8,536	17,855
Downstream of North Las Vegas Detention Basin Diversion Dike	54.4 [b]	0	0	8,536	17,855
Inflow to North Las Vegas Detention Basin	54.4 [b]	2,939	6,751	8,343	8,343
Outflow from Upper Las Vegas Wash Detention Basin	136.3 [c]	2,426	3,888	5,019	19,217
Inflow to Upper Las Vegas Wash Detention Basin	136.3 [c]	3,465	10,312	14,737	24,938

a Storm area is smaller than total tributary area

c Reference 8
d Discharges based on upstream flow splits from hydraulic analysis

If applicable, discuss methods used to determine stillwater elevations and reference the Summary of Stillwater Elevations table:

Not applicable.

3.2 Hydraulic Analyses

State how cross sections were developed for all streams studied by detailed methods:

Cross sections were developed from four primary sources:

- aerial photogrammetry;
- field surveys;
- as-built plans for flood control facilities; and
- improvement plans for streets, bridges and development areas.

Aerial photogrammetry was used to develop topographic maps of the study area with a contour interval of 4 feet (Reference 13). Cross sections were developed by photogrammetric methods for most of the upper portion of the study area where there are few flood control channel improvements. Additional cross sections were developed directly from the aerial topographic mapping where determined necessary based on preliminary hydraulic analyses. Additional field surveys were conducted to obtain elevations for the bridge crossings of Upper Las Vegas Wash at Lone Mountain Road, Craig Road, and the Union Pacific Railroad Bridge. Field surveys were also conducted to increase the density of topographic data near the intersection of Losee Road and Lone Mountain Road, where flows from the wash cross Losee Road in two low water crossings. As-built plans for the King Charles Channel (References 14, 15), Improvements for 142 acres at Losee Road and Craig Road (Reference 16), Lone Mountain Road Bridge (Reference 17), North Las Vegas Detention Basin (Reference 18), Upper Las Vegas Wash Detention Basin and Interception Berm/Channel (Reference 19) were used to develop cross sections in these areas.

The following table describes the cross section data used:

Cross Section Station	**Data Source**
1+50 to 37+20	As-built plans - King Charles Diversion Channel Phase 1
37+20 to 58+53	As-built plans - King Charles Diversion Channel Phase 2; field survey at UPRR bridge
58+53 to 86+82	As-built improvement plans - 142 acre development at Losee Road and Craig Road; field survey at Craig Road bridge

87+80 to 88+61	As-built plans - Lone Mountain Road Bridge; field survey at Lone Mountain Road bridge; As-built improvement plans - 142 acre development and Losee Road and Craig Road
91+20	Aerial photogrammetry
92+37 to 94+29	Aerial topographic mapping
101+55 to 141+67	Aerial photogrammetry
143+68	Aerial topographic mapping
151+14	Aerial photogrammetry
156+67	Aerial topographic mapping
165+46 to 184+36	Aerial photogrammetry
184+62 to 192+15	Aerial topographic mapping
198+02 to 263+83	Aerial photogrammetry
270+00 to 273+03	Aerial topographic mapping
289+03 to 309+35	As-built plans - Las Vegas Detention Basin Flood Control Project
312+35 to 315+00	Aerial topographic mapping
320+44 to 555+70	Aerial photogrammetry
560+10 to 564+87	As-built plans - Upper Las Vegas Detention Basin and Interception Berm/Channel
59+059 to 749+97	Aerial photogrammetry

Describe how the dimensions of hydraulic structures were determined:

The dimensions of major hydraulic structures, including the outlet dams and outlet works for the two detention basins and their interception and diversion channels, were determined from as-built drawings. Field surveys were completed at all bridge crossings.

Explain how channel roughness factors (Manning's "n") were assigned. The "n" values for ALL streams studied by detailed methods (channel and overbank areas) should be given:

Channel roughness factors were determined based on standard hydraulic engineering references (References 20, 21), engineering judgment, and field observations. Limited sensitivity testing was conducted during hydraulic modeling to determine the effect of a range of 'n' values on model results. Final model roughness values were selected to represent a combination of roughness due to vegetation, bed and bank material, and bed form irregularity. The depth of flow was also considered in selecting appropriate 'n' values. The following Manning's 'n' values were assigned to various channel and overbank areas:

Channel/Overbank Type	**Manning's 'n'**
Concrete lined channel	0.014 to 0.017
Developed overbanks (Primarily pavement areas, smooth earth, or sparse landscaping)	0.030 to 0.035
Earth channels (constructed)	0.030
Unimproved wash channels (with vegetation)	0.040 to 0.045
Industrial lots (with obstructions)	0.045

State how water surface elevations were obtained for all streams studied by detailed methods:

The US Army Corps of Engineers HEC-2 program (Reference 22) was used as the primary tool for computation of water surface profiles for this study. This model was run in both subcritical and supercritical modes for various reaches of the study area. The results of the HEC-2 model were supplemented by independent calculations at bridges and culverts using the Federal Highway Administration HY-8 program (Reference 23) and by hand. Shallow overbank flooding depths and velocities were computed in some areas by hand using normal depth computations from Manning's equation.

Flood profiles were drawn showing computed water surface elevations for floods of the selected recurrence intervals. The 10- and 50-year peak discharges on the "A" Channel were found to produce backwater in the lower portion of the King Charles Channel with higher water surface elevations than HEC-2 models for the corresponding recurrence intervals on the King Charles Channel. The water surfaces from backwater on the "A" Channel are shown in the profiles for these recurrence intervals. Maximum basin stages in the North Las Vegas Detention Basin and Upper Las Vegas Detention Basin computed using the HEC-1 models, produced higher water surface elevations for the 50-, 100-, and 500-year flood events than the HEC-2 models for the portions of the wash immediately upstream of the basins. These elevations are reflected on the profiles.

The starting water surface elevations for the Upper Las Vegas Wash at the confluence with the "A" Channel were calculated using the slope area method. Water surface elevations at the "N" Channel were computed using supercritical profiles. These starting water surfaces match the water surface elevations calculated at the diversion from the King Charles Channel. Starting water surface elevations at the North Las Vegas Detention Basin were derived from HEC-1 routing of flows through the basin. The starting water surface elevations were taken as the basin stage at the time of the peak discharge. The starting water surface elevations in Upper Las Vegas Detention Basin were computed using the same methods.

The hydraulic analyses for this study were based on unobstructed flow through the wash and hydraulic structures except at Lone Mountain Road Bridge. Lone Mountain Road Bridge is the first bridge that Upper Las Vegas wash passes through moving downstream, and is subject to high debris and sediment loads from the wash. The bridge is subject to pressure flow at the 100- and 500-year peak discharges. Under these conditions, the capacity of the bridge to transport large bed load sediments will be less than the capacity of the inflowing channel. Due to the high availability of cobble sized bed load that can be generated by progression of existing headcuts upstream of the bridge, the bridge opening was assumed blocked during the 100- and 500-year peak discharges.

The HEC-2 models and the HY-8 program were used to define the locations where channel and hydraulic structure capacities were inadequate to convey the peak flood discharges for various recurrence intervals. Where overbank flows remained hydraulically connected to the main wash or channel flows, the overbank flows were modeled with HEC-2, and the results used to delineate AE flood hazard zones. Where breakout flows were determined likely to become hydraulically separated from the main wash or channel, the breakout flow depths and velocities were estimated using normal depth computations, and the results of these computations used to delineate AO flood hazard zones. Breakout flows occur at

the 100- and 500-year flood discharges near Azure and Losee Road, Lone Mountain Road, Craig Road, and the UPRR Bridge. A portion of these flows return to the main channel downstream in various locations within the study area. Overflow magnitudes were determined using HEC-2 and hand calculations. For determination of the profiles in the main channel or wash downstream of breakout flows, the overflow was subtracted from the total flow upstream. Flows in the HEC-2 models decrease in a downstream direction as overflows are progressively subtracted from the main flow area at subsequent breakout locations.

Average 100-year flow depths in overflow areas were determined using normal-depth calculations. Areas of inundation for the 500-year flood discharge were determined by approximate methods using a combination of normal depth calculations, review of available topographic mapping, and field observation.

Shallow flooding is often characterized by highly unpredictable flow directions caused by low relief or shifting channels and high debris loads. Where such conditions exist, the entire area susceptible to this unpredictable flow was delineated as a zone of equal risk. Small scale topographic variations were averaged across inundated areas to determine flood depths.

Describe the methodology for wave height/runup, lacustrine, ice jam, alluvial fan flooding, and shallow flooding areas (where applicable):

Not applicable.

If applicable, reference the Transect Descriptions which should include: transect number, location, 100-year stillwater elevation, and maximum 100-year wave elevation.

Not applicable.

If performed, describe the hydraulic analyses for the approximate flooding sources:

No approximate flooding sources studied.

If applicable, reference the Transect Data Table which should include: Flooding Source (with the affected transects), 10-, 50-, 100-, and 500-year stillwater elevation, zone designation and Base Flood Elevation.

Not applicable.

If applicable, reference the Transect Location Map.

Not applicable.

Standard paragraphs in this section include paragraphs for cross sections, NGVD, and unobstructed flow.

No modifications required to standard paragraphs, except Lone Mountain Road Bridge assumed blocked for the 100- and 500-year peak discharges as described above.

Specify whether elevations are referenced to NGVD or NAVD or other datum, and give releveling dates, if any.

All elevations are referenced to NGVD (1929).

4.0 FLOODPLAIN MANAGEMENT APPLICATIONS

4.1 Floodplain Boundaries

Identify all maps used. Include the scale, contour interval, and type of map (topographic, compiled from aerial photographs, etc):

Flood boundaries for the 100- and 500-year flood events in the Upper Las Vegas Wash were delineated on 1:4,800 scale topographic map with a contour interval of 4 feet (reference 24). Flood boundaries for the 500-year flood event located outside the extent of this mapping were delineated on the topographic mapping developed for the City of North Las Vegas at a scale of 1:4,800 with a contour interval of 2 feet (reference 25) and USGS quadrangle topographic maps, 1:24,000 (reference 26 and 27).

Cross sections within the unimproved areas of the wash were obtained by aerial photogrametry and interpolated from topographic maps. Cross sections at structures were obtained from as-built plans and verified by field inspections and surveys.

There is a datum difference between the NGVD 1929 and NAVD 1988 mapping from ranging 2.41 to 2.46 feet in the Upper Las Vegas Wash. The average difference between the control points was 2.43 feet. Therefore, 2.43 feet was subtracted from the photogrametric control and the ERM elevations to convert from NAVD 1988 to NGVD 1929. Cross section elevations obtained from NAVD 1988 topographic mapping used in the hydraulic models were converted to NGVD 1929 by subtracting 2.4 feet.

Identify and reference all maps or methods used to delineate floodplain boundaries for approximate flooding sources:

Not applicable.

4.2 Floodways

List streams, if any, for which floodway widths extend beyond the corporate limits:

No floodway determined.

List streams affected by backwater:

The lower portion of the King Charles Channel is affected by backwater from the "A" Channel for the 10- and 50-year peak discharges. These two channels have their confluence at the study area downstream boundary near Interstate 15. The "A"Channel backwater elevations for the 10- and 50-year peak discharges were extended upstream to intersect with the computed water surface elevations in the King Charles Channel for the corresponding recurrence intervals.

Provide method used for floodway computations:

No floodway determined.

Give reason why no floodway was delineated for streams or portions of streams:

Determination of a floodway was discussed, but not requested by community at the initial CCO meeting, due to anticipated confinement of 100-year flood in natural and constructed channel boundaries. The FEMA Project Officer agreed that a floodway was not required.

Identify any abnormal procedures (such as state-imposed surcharges of less than 1.0 foot) for floodway delineations:

No abnormal procedures.

7.0 OTHER STUDIES

Identify and reference all other FISs for contiguous communities and any other published reports or available data dealing with related flooding sources. All disagreements and discrepancies must be noted and resolved:

This report is for a restudy of one of the streams covered in the current Flood Insurance Study for Clark County, Nevada and Incorporated Areas (Reference 4). Changes in discharges and water surface profiles in this study are due to the recent construction of flood control facilities.

Introduction to Volume 7

This volume of the TSDN contains mapping information pertaining to the study, including a description of mapping sources, base maps, aerial photographs, a mapping reference list, and a description of the photogrammetric processes used in the study. The study was completed for two cases due to uncertainty regarding the performance of the North Las Vegas Detention Basin Diversion Dike during a major flood event. This volume contains mapping information relevant to both study cases.

Study Contractor: Northwest Hydraulic Consultants, Inc.

Mapping Information

Compilation of the work and base maps were developed from several sources. The NGVD 1929 datum was selected by NHC and the Project Officer as the datum for the FIS.

Kenney Aerial Mapping was subcontracted by NHC to develop 1 inch = 400 feet scale topographic maps at a contour interval of 4 feet, photography date February 1996. Initially, cross sections for the HEC-2 models were obtained from the February 1996 aerial photogrametry. Spot elevations at structures and along roads were obtained using both aerial photogrametry and field surveys. Additional cross sections were added using the 4' contour interval aerial topographic mapping and 2' contour interval aerial topographic mapping developed by Kenney Aerial Mapping for the City of North Las Vegas, March 1995. As-built plans for the Upper Las Vegas Detention Basin, North Las Vegas Detention Basin, Lone Mountain Road Bridge, 142 Acre Site at Losee and Craig Road, Craig Commercial Site, King Charles Diversion Channel from N-Channel Phase 1 and 2 were also used to develop cross sections and determine the potential flood routes in their respective areas. USGS quadrangle maps NE Las Vegas and Valley were used to map the Without Diversion Dike conditions for the 500-year flood event.

Sections, corporate and city limits were obtained from the City of North Las Vegas (CNLV) and the City of Las Vegas (CLV) GIS. The city limits between the these two cities did not coincide at many locations, overlapping in areas and leaving gaps between the limits in other areas. NHC discussed the discrepancies between the city limits with the GIS departments of both cities. The City of North Las Vegas GIS Specialist informed NHC the city limits for City of North Las Vegas were entered into GIS by digitizing limits from Accessors' Parcel Maps. NHC was told by the City of Las Vegas GIS that the CLV maps were determined by legal descriptions. Therefore, the CLV limits were used where possible. Additional mapping such as the effective firm maps for this area were used to confirm corporate and city limits.

Hydrologic modeling for this study was limited to revising adopted HEC-1 models to reflect current conditions. Therefore it was not necessary to obtain soil and vegetation maps for this study.

File name: MD_BWMW.ME

METADATA FILE
Upper Las Vegas Wash With
North Las Vegas Detention Basin Diversion Dike

Data Set Identity:	Base and Work Maps
County and State:	Clark County, Nevada
Theme Keywords:	Base and Work Maps
Representation Model:	Vector
Spatial Object Types:	Point, node, tic, arc, polyline & block
Data Set Size:	
Transfer Format:	DWG
Data Set Description:	Base and Work Maps Files
Intended Use:	Delineate Area of Flood Hazard
Data set extent:	36.316, 115.207, 36.336, 115.287 North American Datum of 1983

Re: Upper North Las Vegas Wash Metadata

Zeiss RMK TOP 15 with Gyromount and Forward Motion Compensation -- Focal Length 6"
"USGS Calibration Report Follows dated January 10, 1995"

Photo Scale 1:14400 Photo Date 2-6-96

An 1800 C Factor for Four Foot Contours

Manufacturers Recommended C Factor is 2400 for a Zeiss P3 Analytical Stereoplotters

P3's are self calibrating therefore the request is N/A

Please let me know if you need any additional information.

Sincerely,

John Cahoon

REPORT OF CALIBRATION
of Aerial Mapping Camera

January 10, 1995

Camera type: Zeiss RMK Top 15*
Lens type: Zeiss Pleogon A3/4
Nominal focal length: 153 mm

Camera serial no.: 141299
Lens serial no.: 141334
Maximum aperture: f/4
Test aperture: f/4

Submitted by: Kenney Aerial Mapping Company
Phoenix, Arizona

Reference: Carl Zeiss, Inc., purchase order No. 337-950024, dated January 11, 1995.

These measurements were made on Kodak Micro-flat glass plates, 0.25 inch thick, with spectroscopic emulsion type 157-01 Panchromatic, developed in D-19 at 68° F for 3 minutes with continuous agitation. These photographic plates were exposed on a multicollimator camera calibrator using a white light source rated at approximately 5200K.

I. Calibrated Focal Length: 153.966 mm

II. Lens Distortion

Field angle:	7.5°	15°	22.7°	30°	35°	40°
Symmetric radial (um)	0	0	1	1	1	-1
Decentering (um)	0	0	1	1	2	3

Symmetric radial distortion parameters

$K_0 = 0.2789 \times 10^{-5}$
$K_1 = -0.4689 \times 10^{-8}$
$K_2 = 0.3049 \times 10^{-12}$
$K_3 = 0.0000$
$K_4 = 0.0000$

Decentering distortion parameters

$P_1 = -0.1661 \times 10^{-6}$
$P_2 = -0.5452 \times 10^{-8}$
$P_3 = 0.0000$
$P_4 = 0.0000$

Calibrated principal point

$x_p = 0.005$ mm
$y_p = -0.005$ mm

The values and parameters for Calibrated Focal Length (CFL), Symmetric Radial Distortion (K_0, K_1, K_2, K_3, K_4), Decentering Distortion (P_1, P_2, P_3, P_4), and Calibrated Principal Point [point of symmetry] (x_p, y_p) were determined through a least-squares Simultaneous Multiframe Analytical Calibration (SMAC) adjustment. The x and y-coordinate measurements utilized in the adjustment of the above parameters have a standard deviation (σ) of ±3 microns.

* Equipped with Forward Motion Compensation

United States Department of the Interior

U.S. GEOLOGICAL SURVEY

REPORT OF CALIBRATION
of Aerial Mapping Camera

January 10, 1995

Camera type: Zeiss RMK Top 15*
Lens type: Zeiss Pleogon A3/4
Nominal focal length: 153 mm

Camera serial no.: 141299
Lens serial no.: 141334
Maximum aperture: f/4
Test aperture: f/4

Submitted by: Kenney Aerial Mapping Company
Phoenix, Arizona

Reference: Carl Zeiss, Inc., purchase order No. 337-950024, dated January 11, 1995.

These measurements were made on Kodak Micro-flat glass plates, 0.25 inch thick, with spectroscopic emulsion type 157-01 Panchromatic, developed in D-19 at 68° F for 3 minutes with continuous agitation. These photographic plates were exposed on a multicollimator camera calibrator using a white light source rated at approximately 5200K.

I. Calibrated Focal Length: 153.967 mm

This measurement is considered accurate within 0.005 mm

II. Radial Distortion

Field angle	$\bar{D}_c$	D_c for azimuth angle			
		0° A-C	90° A-D	180° B-D	270° B-C
degrees	um	um	um	um	um
7.5	0	0	0	-1	0
15	0	1	1	-1	-1
22.7	1	2	2	1	-2
30	1	3	0	3	-2
35	1	2	-1	4	-2
40	-2	2	-6	1	-3

The radial distortion is measured for each of four radii of the focal plane separated by 90° in azimuth. To minimize plotting error due to distortion, a full least-squares solution is used to determine the calibrated focal length. $\bar{D}_c$ is the average distortion for a given field angle. Values of distortion D_c based on the calibrated focal length referred to the calibrated principal point (point of symmetry) are listed for azimuths 0°, 90°, 180° and 270°. The radial distortion is given in micrometers and indicates the radial displacement away from the center of the field. These measurements are considered accurate within 5 um.

* Equipped with Forward Motion Compensation

III. Resolving Power in cycles/mm

Area-weighted average resolution: 89

Field angle:	0°	7.5°	15°	22.7°	30°	35°	40°
Radial Lines	134	159	134	95	95	80	95
Tangential lines	134	134	113	80	67	67	80

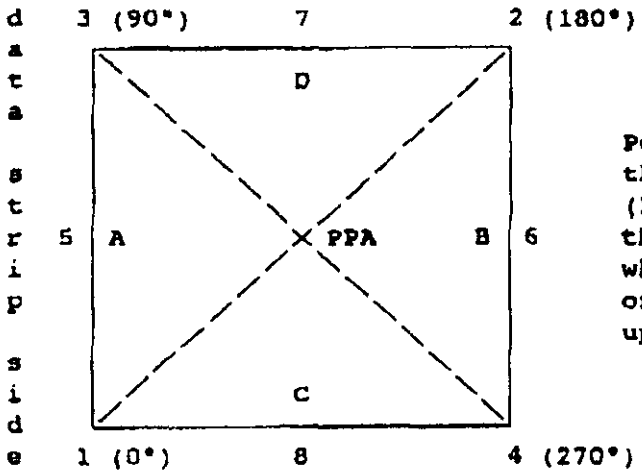
The resolving power is obtained by photographing a series of test bars and examining the resultant image with appropriate magnification to find the spatial frequency of the finest pattern in which the bars can be counted with reasonable confidence. The series of patterns has spatial frequencies from 5 to 268 cycles/mm in a geometric series having a ratio of the 4th root of 2. Radial lines are parallel to a radius from the center of the field, and tangential lines are perpendicular to a radius.

IV. Filter Parallelism

The two surfaces of KL-F (36%) No. 141519 filter accompanying this camera and the USGS TOP 15 test filter KL-F (60%) No. 142399 are within 10 seconds of being parallel. The USGS test filter, in conjunction with the internal "B" filter, was used for the calibration.

V. Shutter Calibration

Indicated exposure time	Effective exposure time	Efficiency
1/100	11.00 ms = 1/90 s	70%
1/200	5.25 ms = 1/190 s	70%
1/300	3.51 ms = 1/285 s	70%
1/400	2.75 ms = 1/365 s	70%
1/500	2.10 ms = 1/475 s	70%



The effective exposure times were determined with the lens at aperture f/4. The method is considered accurate within 3 percent. The technique used is Method I described in American National Standard PH3.48-1972(R1978).

VI. Magazine Platen

The platen mounted in T-MC film magazine No. 137708 does not depart from a true plane by more than 13 um (0.0005 in).

The platen for this film magazine is equipped with an identification marker that will register "141630" in the data strip area for each exposure.

VII. Principal Points and Fiducial Coordinates

Positions of all points are referenced to the principal point of autocollimation (PPA) as origin. The diagram indicates the orientation of the reference points when the camera is viewed from the back, or a contact positive with the emulsion up. The data strip is to the left.

	X coordinate	Y coordinate
Indicated principal point, corner fiducials	-0.002 mm	-0.005 mm
Indicated principal point, midside fiducials	0.005	-0.010
Principal point of autocollimation (PPA)	0.0	0.0
Calibrated principal point (pt. of sym.) x_p, y_p	0.005	-0.005

Fiducial Marks

1	-112.988 mm	-113.004 mm
2	112.993	113.005
3	-113.003	112.985
4	113.008	-113.004
5	-112.993	-0.013
6	113.010	-0.008
7	-0.001	113.009
8	0.012	-112.992

VIII. Distances Between Fiducial Marks

Corner fiducials (diagonals)

1-2: 319.606 mm 3-4: 319.612 mm

Lines joining these markers intersect at an angle of 89° 59' 57"

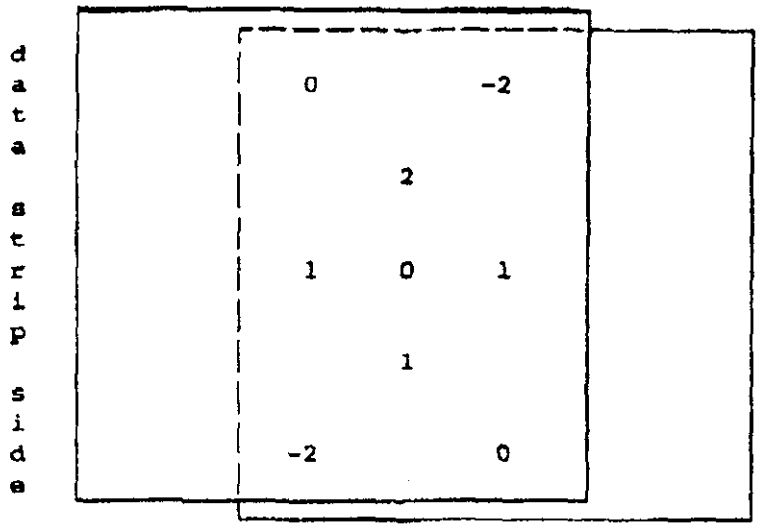
Midside fiducials

5-6: 226.003 mm 7-8: 226.001 mm

Lines joining these markers intersect at an angle of 90° 00' 08"

Corner fiducials (perimeter)

1-3: 225.990 mm 2-3: 225.996 mm



1-4: 225.996 mm 2-4: 226.009 mm

The method of measuring these distances is considered accurate within 0.003 mm

IX. Stereomodel Flatness

Magazine No.: 137708 Base/Height ratio: 0.6

Platen ID: 141630 Maximum angle of field tested: 40°

Stereomodel
Test point array
(values in micrometers)

The values shown on the diagram are the average departures from flatness (at negative scale) for two computer-simulated stereomodels based on comparator measurements on contact glass (Kodak Micro-flat) diapositives made from Kodak 2405 film exposures. These measurements are considered accurate within 5 um.

Re: UPPER LAS VEGAS WASH

Dear Ed,

Enclosed are the survey notes for the GPS control and ERM's, provided to us by CRS and ASSOCIATED CONSULTING. I have also consolidated an ERM list combining the existing monuments within the City of North Las Vegas project and the "new area".

Compilation on the new area is complete and currently being edited. We should be delivering the final maps, CAD, 2x photos and others documents for this portion by February 19 or 20. At that time we can start looking at HECII locations and check profile locations.

We have had trouble re-flying the existing area within the City of North Las Vegas. Due to bad weather and military restrictions we have only completed one of three flight lines in this area. We expect to finish this flying by February 13, 1996 and will complete this mapping with all possible speed.

If you have any questions or if we can be of any further service please do not hesitate to call.

Sincerely,

John Cahoon

ELEVATION REFERENCE MONUMENTS FROM THE CITY OF NORTH LAS VEGAS

NAD83 NAVD88

UPPER LAS VEGAS WASH FLOOD INSURANCE STUDY
KENNEY AERIAL MAPPING, INC. Job Number 960104

The following monument locations and descriptions were originally furnished to KENNEY AERIAL MAPPING, INC. from the CITY OF NORTH LAS VEGAS for use as photogrammetric control. By prior agreement the monument elevations have been converted to NGVD29 by subtracting 2.43 feet from the NAVD88 elevation provided by the CITY. Please see FEMA 37 Appendix 6-2, page A6-5 "Conversion Factor" paragraphs 1 and 2.

Two points with known monument elevations for both datums were used to determine the divergence in the conversion factor between NGVD29 and NAVD88.

CNLV Point Number A-1 at Moccasin and Decatur:

NAVD88 - NGVD29 = 2414.69 - 2411.88= 2.41'+/-

CNLV Point Number L-7 at Pecos and Owens:

NAVD88 - NGVD29 = 1815.08 - 1812.62= 2.46'+/-

The average difference between these points is 2.43 feet which was used to convert the photogrammetric control and the ERM elevations. The greatest divergence is less than .1' (i.e. .05'), allowing us to use the average difference throughout the City of North Las Vegas. Some differences exist between Monument Elevations and Panel Point (Ground) Elevations. These differences are noted below.

The study area not covered by existing photography and control, i.e. everything west of Decatur Boulevard, has been controlled in the field by GPS methods to NAD83 and NGVD29. These points conform to First Order (Order C) specifications (1:100,000).

LEAST SQUARES ADJUSTMENTS

FILLNET(tm) is a least squares adjustment program written by T. Vincenty, formerly a geodesist with the Geodetic Research and Development Laboratory, National Geodetic Survey, NOS, NOAA, specifically for adjusting GPS observations in support of geodetic network densifications.

A thorough treatment of the concepts and mathematical model behind **FILLNET** can be found in an article on page 103 of the ACSM publication "Surveying and Mapping", June 1987.

FILLNET(tm) is unique in 2 significant respects. First it properly treats the type of work we've performed for you as an extension of the National Geodetic Reference System (NGRS). Secondly it uses **a-priori** weight estimations instead of the incomplete covariance model developed during initial GPS vector reductions, for modeling measurement errors. This is important because of deformations existing in and between the NGRS and the GPS satellite frame. Error in GPS vectors is treated as having a fixed component in x,y,z and a length dependent proportional component.

The most important information contained in the results of your adjusted GPS vectors are organized in 7 sections of data output and will be briefly explained in the following paragraphs.

SECTION 1.

PRELIMINARY COORDINATES:

	LAT.	LON.	ELEV.	G.H.	CONSTR.

LAT., LON. and ELEV. are initial estimates of the geodetic coordinates obtained either from published information or from the baseline reduction software. G.H., if present, is an estimate of the geoid height obtained from the NGS North American model. A geoid model has 2 components; an actual height above or below the ellipsoid and a tilt or slope between points. In rare circumstances standard errors will be assigned to a preliminary coordinate allowing that point to change. An example might occur when including NGRS 1st Order and 3rd Order points in a network; we might want the 3rd Order point to float within given limits.

SECTION 2.

VECTORS:

	DX	DY	DZ	LENGTH	ERROR CODES

Here are the measured Earth Centered Fixed (E.C.F.) coordinate differences in meters between the base and roving receiver obtained from postprocessing. The line length is a mark-to-mark 3-D value. Error codes express the **a-priori** fixed and proportional parts-per-million in the $\Delta x, \Delta y, \Delta z$ and length components. Weighting is very similar to the method used for EDM line lengths.

SECTION 3.

SHIFTS:

Shifts are expressed in meters in your local North, East, Elevation system. They indicate how much the preliminary coordinate has moved to get to its adjusted value. These numbers are usually small. One exception is when the initial reduction was done on the ellipsoid and the final elevations are linked to geoid heights and benchmarks. Then shifts are usually in the 20 to 30 meter range.

When verifying a number of NGRS stations we enter published values for preliminary coordinates, hold a minimum number fixed and examine the shifts as part of the quality control testing of fixed control.

SECTION 4.

ADJUSTED VECTORS, GROUP 1:

DX,DY,DZ V DN,DE,DU v v'

DX,DY,DZ express adjusted vector differences relative to measured values and are expressed in E.C.F. coordinate terms. V is the residual, which is the difference between the adjusted and measured values. These should be very small, 0.050 meter or less. E.C.F. coordinates are very hard to visualize because X,Y,Z only translate directly into values on the ground how a user would picture them at the North and South poles. FILLNET has computed the center of your project and rotated the vectors into the local geodetic horizon system. DN,DE,DU are the X,Y,Z, vectors translated into meaningful values along with their residuals, v. v' is the normalized residual which is a function of the weighted residual. v' is extremely useful in detecting bad vector components. We normally like to see any v' less than 3.0.

SECTION 5.

S.E. OF UNIT WEIGHT = 1.006

NUMBER OF -

OBS. EQUATIONS	115
UNKNOWNS	58
DEGREES OF FREEDOM	57
ITERATIONS	0

Standard Error of Unit Weight is the sum of the residuals squared divided by the degrees of freedom (redundancy), $_v /(m-n)$. The closer to 1.000 this value is, we then can say with a high degree of confidence we've weighted the vectors and developed the error model correctly. When comparing a minimally and fully fully constrained adjustment this value will usually show an increase under full constraint. If there are no systematic errors in the local coordinate system this value should not increase by more than 1.5 times the minimally constrained value.

OBS. EQUATIONS are the total GPS $_x,_y,_z$ values observed, UNKNOWNS are the number of new LAT.,

LON., ELEV. triplets being solved for and DEGREES OF FREEDOM are the number of observations minus the number of unknowns (m-n). Conventional surveying takes measured angles and distances and forms a series of nonlinear equations that are iterated in an adjustment until they converge in a solution. GPS observations are simple differences and the model is closely linear therefore iteration is rarely necessary. If the shifts indicate the PRELIMINARY COORDINATES were off by 50 meters or so, an iteration may be necessary and will be indicated in the ITERATIONS.

SECTION 6.

ADJUSTED POSITIONS:

LAT. LON. ELEV. STD. ERRORS (m)

LAT., LON. and ELEV. are the final adjusted coordinates. ELEV. may be either ellipsoidal or orthometric heights, depending on your project specifications. ***WARNING*** Elevations may appear to be orthometric elevations when in fact they are not. When specifications don't require precise elevations, we usually approximate orthometric heights in order to obtain the best state plane coordinate conversion factors possible. STD. ERRORS (m) are the linear components of the 3 error ellipsis centering on each point for the 1_ or 68.3% probability level. The 2_ or 95% confidence level is obtained by multiplying these standard errors by 1.96. 10ppm 2_ would be met by 5.1 ppm 1_ accuracies.

SECTION 7.

ACCURACIES (m):

D. LAT. D. LON. VERT.

The accuracies are the 1_ estimates of the error in each of the 3 components of the selected baselines. Baseline lengths are reduced to their mark-to-mark slope distances by the postprocessing software in the E.C.F. coordinate system. FILLNET rotates and translates these into the more meaningful differences of LAT., LON. and ELEV.

FULLY CONSTRAINED
LEAST SQUARES ADJUSTMENT

Used to connect the GPS network to the local control and test for distortions and systematic error.

This adjustment produces the final geodetic coordinates which are then converted to State Plane Coordinates in the selected State and Zone.

VERTICAL CONTROL ANALYSIS

PN 1269 - CRS CONSULTING ENGINEERS - FEMA PHOTOCONTROL

Vertical control for this project is referred exclusively to benchmark V 169.

V 169 is a National Geodetic Survey First Order benchmark and part of the level line running from Las Vegas through the Nevada Test Site, Beatty, Tonopah to Reno. It is published in both NVD29 and NVD88 datums.

The City of Las Vegas ran level loops through the project area in 1990. Table 1 indicates the published elevations of 8 City benchmarks observed as part of this project.

City benchmarks were established on BLM brass cap monuments attached to a 2"x 24" aluminum pipe set approximately 2' into the ground. The NGS benchmark is a 12"x 12" concrete column sunk over 4' down. Long term stability is a prime factor when NGS establishes a monument.

We've noted the published City elevations average 0.11' higher than our measurements, indicating either a settlement or ground subsidence on the City monuments or the NGS monument has risen in elevation; we belive the former has occurred.

Additionally, we are aware of a 0.08' closure discrepency between the City benchmarks with a line of leveling run by Clark County along Tonopah Highway. This occurrs at Ann Road.

If there is reason to adopt the City datum in preference to the NGS datum for this project we will be pleased to readjust the entire network at no additional charge.

ADJUSTED COORDINATE DATA

NAD83 HORIZONTAL AND NVD29 VERTICAL

Contains Geographic and State Plane Coordinates

Additional coordinate information including;
precise and mean scale, elevation and combined factors.

Program NAD83 RUN DATE: 01/23/1996 RUN TIME: 16:51:25

PROJECT: PN 1269 - CRS Conulting Engineers - FEMA Mapping Control
SURVEYED BY: Associated Consulting Inc. - Las Vegas, Nevada
DATES OBSERVED: 20-23 January 1996
POSTPROCESSED: 22-23 January 1996

HORIZONTAL GEODETIC DATA BASED ON THE NAD83 DATUM
VERTICAL GEODETIC DATA BASED ON THE NVD29 DATUM

ADJUSTED COORDINATE DATA

NAD83 HORIZONTAL AND NVD88 VERTICAL

Contains Geographic and State Plane Coordinates

Additional coordinate information including;
precise and mean scale, elevation and combined factors.

Program NAD83 RUN DATE: 01/24/1996 RUN TIME: 09:42:08

PROJECT: PN 1269 - CRS CONSULTING ENGINEERS - FEMA PHOTOCONTROL
SURVEYED BY: Associated Consulting Inc. - Las Vegas, Nevada
DATES OBSERVED: 20-22 January 1996
POSTPROCESSED: 20-23 January 1996

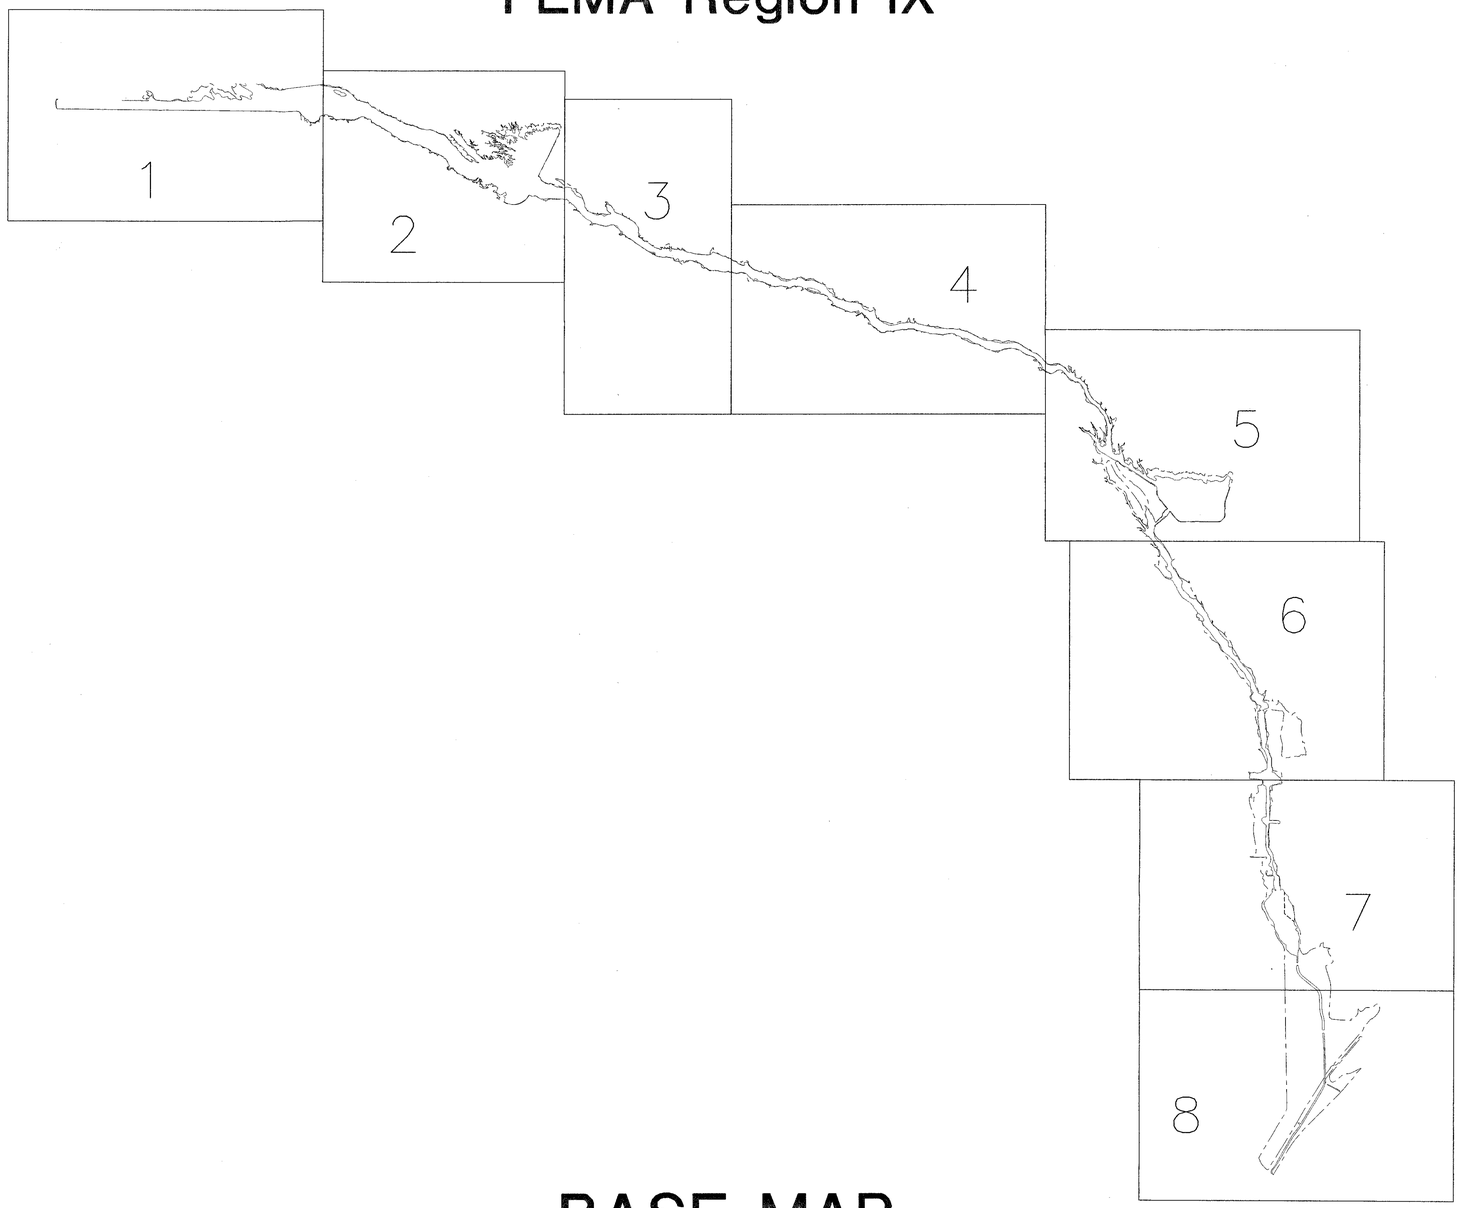
MONUMENT DESCRIPTIONS

MONUMENT DESCRIPTIONS

PN 1269 - CRS CONSULTING ENGINEERS - FEMA PHOTOCONTROL



23 January 1996

POINT	DESCRIPTION	NVD88 m.	NVD29 ft.
0802	Clark Co. GIS mon. in conc. marked "0802" at Buffalo/Moccasin.		
0803	Clark Co. GIS mon. in conc. marked "0803" at Decatur/Moccasin.		
ER01	Brass cap in conc. marked "LS 1919". CLV BM 1LV90 5NES	772.477	2531.96
ER02	BLM B/C marked " S5/S8|S4/S9 T19S R60E 1990 CLV BM " in A/C. CLV BM 1LV90 8NES	771.970	2530.28
ER03	Alum. mon..marked " CLV 1/4 S4|S3 ". BM 1LV90 3W4	748.183	2452.25
ER04	CLV BM. Rivet and plate in conc. marked " CITY OF LAS VEGAS BM NO." (Not the BM listed in CLV bench book.)		
ER05	Brass cap in 3/4" I.P.. marked " 35/2|36/1 RLS 1919 1990 T18S R60E ". CLV BM 1LV90 2NES	732.566	2401.02
ER06	CLV BM. Rivet and plate in conc. marked " CLV BM NO. " (Not the BM listed in CLV bench book.)		
ER07	Set lead and brass tag in SE cor. of outflow marked " LS 5876 ".		
FP01	#5 Rebar w/ plastic cap marked "LS 5876". Flush w/ surf.		
FP02	#5 Rebar w/ plastic cap marked "LS 5876". Flush w/ surf.		
FP03	#5 Rebar w/ plastic cap marked "LS 5876". Flush w/ surf.		
FP04	#5 Rebar w/ plastic cap marked "LS 5876". Flush w/ surf.		
FP05	#5 Rebar w/ plastic cap marked "LS 5876". Flush w/ surf.		
FP06	BLM B/C marked " W1/16 S34|S3 1990 ". CLV BM 1LV90 3NNW6. 15cm. above surf.	752.165	2465.32
FP07	BLM B/C.marked " C1/4 S3 1990 ". 15cm. above surf.		
FP08	BLM B/C marked " S3/S34|S2/S35 T18S T19S R60E 1990 ". CLV BM 1LV90 3NES. 10cm. above surf.	740.199	2426.06
FP09	BLM B/C marked " 1/4 S3|S2 T19S R60E 1990 ". CLV BM 1LV90 2W4. 15cm above surf.	741.056	2428.87
FP10	#5 Rebar w/ plastic cap marked "LS 5876".		
FP11	#5 Rebar w/ plastic cap marked "LS 5876".		
FP12	#5 Rebar w/ plastic cap marked "LS 5876".		
FP13	#5 Rebar w/ plastic cap marked "LS 5876".		
FP14	BLM B/C marked " N1/16 S12|S7 1190 ". CLV BM 1LV90 12NEE6. 15cm. above surf.	715.054	2343.56
FP15	#5 Rebar w/ plastic cap marked "LS 5876".		
FP16	#5 Rebar w/ plastic cap marked "LS 5876".		
NE01	BLM B/C marked " S36/S1|S31/S6 T18S R60E T19S R61E 1990 " 10cm above surf.		
V169	USC&GS B/C in conc. marked " V169 1935 ".	791.316	790.582 (2593.77)

NOTES:

1. Points ER01 through ER07 are the ERM reference monuments.
2. Points FP01 through FP16 are the photocontrol panel points.
3. NE01 is the BLM brass cap at the NE cor. of Sec. 1 at Decatur/Moccasin which is a check point with other photocontrol.

Introduction to Volume 8

This volume of the TSDN contains copies of the work maps and reference maps. The study was completed for two cases due to uncertainty regarding the performance of the North Las Vegas Detention Basin Diversion Dike during a major flood event. This volume contains the work maps and reference maps for the '**With North Las Vegas Detention Basin Diversion Dike**' case. Volume 9 contains similar information for the "Without North Las Vegas Detention Basin Diversion Dike'. A discussion of the evaluation of the diversion dike and other flood control structures in the study area is included in Volume 2.

TSDN - Flood Insurance Study

Upper Las Vegas Wash
City of Las Vegas, City of North Las Vegas, Unincorporated Areas of Clark County
EMW - 95 - C - 4840

Introduction to Volume 9

This volume of the TSDN contains copies of the work maps and reference maps. The study was completed for two cases due to uncertainty regarding the performance of the North Las Vegas Detention Basin Diversion Dike during a major flood event. This volume contains the work maps and reference maps for the '**Without North Las Vegas Detention Basin Diversion Dike**' case. Volume 9 contains similar information for the "With North Las Vegas Detention Basin Diversion Dike'. A discussion of the evaluation of the diversion dike and other flood control structures in the study area is included in Volume 2.

NOTE:
THE NORTH LAS VEGAS DETENTION BASIN DIVERSION DIKE WEIR WAS OVERTOPPED BY THE 100 YEAR FLOW. THEREFORE, THE DIKE AND THE DETENTION BASIN WERE NOT INCLUDED IN THE ANALYSES FOR THE PURPOSE OF DETERMINING PEAK FLOWS DOWNSTREAM. THE 100 YEAR AND 500 YEAR FLOWS AT THIS POINT ARE 8536cfs AND 17,855cfs WITHOUT THE DIKE.
